(54) Title: PROTEINS AND NUCLEIC ACIDS ENCODING SAME

(57) Abstract: Disclosed herein are nucleic acid sequences that encode novel polypeptides. Also disclosed are polypeptides encoded by these nucleic acid sequences, and antibodies, which immunospecifically-bind to the polypeptide, as well as derivatives, variants, mutants, or fragments of the aforementioned polypeptide, polynucleotide, or antibody. The invention further discloses therapeutic, diagnostic and research methods for diagnosis, treatment, and prevention of disorders involving any one of these novel human nucleic acids and proteins.

## PROTEINS AND NUCLEIC ACIDS ENCODING SAME

### FIELD OF THE INVENTION

The invention generally relates to nucleic acids and polypeptides encoded thereby.

5

### BACKGROUND OF THE INVENTION

The invention generally relates to nucleic acids and polypeptides encoded therefrom. More specifically, the invention relates to nucleic acids encoding cytoplasmic, nuclear, membrane bound, and secreted polypeptides, as well as vectors, host cells, antibodies, and recombinant methods for producing these nucleic acids and polypeptides.

10

### SUMMARY OF THE INVENTION

15

The invention is based in part upon the discovery of nucleic acid sequences encoding novel polypeptides. The novel nucleic acids and polypeptides are referred to herein as NOVX, or NOV1-99 nucleic acids and polypeptides. These nucleic acids and polypeptides, as well as derivatives, homologs, analogs and fragments thereof, will hereinafter be collectively designated as "NOVX" nucleic acid or polypeptide sequences.

20

In one aspect, the invention provides an isolated NOVX nucleic acid molecule encoding a NOVX polypeptide that includes a nucleic acid sequence that has identity to the nucleic acids disclosed in SEQ ID NOS:2n-1, wherein n is an integer between 1 and 162. In some embodiments, the NOVX nucleic acid molecule will hybridize under stringent conditions to a nucleic acid sequence complementary to a nucleic acid molecule that includes a protein-coding sequence of a NOVX nucleic acid sequence. The invention also includes an isolated nucleic acid that encodes a NOVX polypeptide, or a fragment, homolog, analog or derivative thereof. For example, the nucleic acid can encode a polypeptide at least 80% identical to a polypeptide comprising the amino acid sequences of SEQ ID NOS:2n, wherein n is an integer between 1 and 162. The nucleic acid can be, for example, a genomic DNA fragment or a cDNA molecule that includes the nucleic acid sequence of any of SEQ ID NOS:2n-1, wherein n is an integer between 1 and 162.

25

30

Also included in the invention is an oligonucleotide, *e.g.*, an oligonucleotide which includes at least 6 contiguous nucleotides of a NOVX nucleic acid (*e.g.*, SEQ ID NOS:2n-1, wherein n is an integer between 1 and 162) or a complement of said oligonucleotide.

Also included in the invention are substantially purified NOVX polypeptides (SEQ ID NOS:2n, wherein n is an integer between 1 and 162). In certain embodiments, the NOVX polypeptides include an amino acid sequence that is substantially identical to the amino acid sequence of a human NOVX polypeptide.

5       The invention also features antibodies that immunoselectively bind to NOVX polypeptides, or fragments, homologs, analogs or derivatives thereof.

In another aspect, the invention includes pharmaceutical compositions that include therapeutically- or prophylactically-effective amounts of a therapeutic and a pharmaceutically-acceptable carrier. The therapeutic can be, *e.g.*, a NOVX nucleic acid, a NOVX polypeptide,  
10       or an antibody specific for a NOVX polypeptide. In a further aspect, the invention includes, in one or more containers, a therapeutically- or prophylactically-effective amount of this pharmaceutical composition.

In a further aspect, the invention includes a method of producing a polypeptide by culturing a cell that includes a NOVX nucleic acid, under conditions allowing for expression  
15       of the NOVX polypeptide encoded by the DNA. If desired, the NOVX polypeptide can then be recovered.

In another aspect, the invention includes a method of detecting the presence of a NOVX polypeptide in a sample. In the method, a sample is contacted with a compound that selectively binds to the polypeptide under conditions allowing for formation of a complex  
20       between the polypeptide and the compound. The complex is detected, if present, thereby identifying the NOVX polypeptide within the sample.

The invention also includes methods to identify specific cell or tissue types based on their expression of a NOVX.

Also included in the invention is a method of detecting the presence of a NOVX  
25       nucleic acid molecule in a sample by contacting the sample with a NOVX nucleic acid probe or primer, and detecting whether the nucleic acid probe or primer bound to a NOVX nucleic acid molecule in the sample.

In a further aspect, the invention provides a method for modulating the activity of a NOVX polypeptide by contacting a cell sample that includes the NOVX polypeptide with a  
30       compound that binds to the NOVX polypeptide in an amount sufficient to modulate the activity of said polypeptide. The compound can be, *e.g.*, a small molecule, such as a nucleic acid, peptide, polypeptide, peptidomimetic, carbohydrate, lipid or other organic (carbon containing) or inorganic molecule, as further described herein.

Also within the scope of the invention is the use of a therapeutic in the manufacture of a medicament for treating or preventing various disorders or syndromes described below.

The therapeutic can be, *e.g.*, a NOVX nucleic acid, a NOVX polypeptide, or a NOVX-specific antibody, or biologically-active derivatives or fragments thereof.

5       For example, the compositions of the present invention will have efficacy for treatment of patients suffering from the diseases and disorders disclosed above and/or other pathologies and disorders of the like. The polypeptides can be used as immunogens to produce antibodies specific for the invention, and as vaccines. They can also be used to screen for potential agonist and antagonist compounds. For example, a cDNA encoding NOVX may be useful in  
10       gene therapy, and NOVX may be useful when administered to a subject in need thereof. By way of non-limiting example, the compositions of the present invention will have efficacy for treatment of patients suffering from the diseases and disorders disclosed above and/or other pathologies and disorders of the like.

      The invention further includes a method for screening for a modulator of disorders or  
15       syndromes including, *e.g.*, the diseases and disorders disclosed above and/or other pathologies and disorders of the like. The method includes contacting a test compound with a NOVX polypeptide and determining if the test compound binds to said NOVX polypeptide. Binding of the test compound to the NOVX polypeptide indicates the test compound is a modulator of activity, or of latency or predisposition to the aforementioned disorders or syndromes.

20       Also within the scope of the invention is a method for screening for a modulator of activity, or of latency or predisposition to disorders or syndromes including, *e.g.*, the diseases and disorders disclosed above and/or other pathologies and disorders of the like by administering a test compound to a test animal at increased risk for the aforementioned disorders or syndromes. The test animal expresses a recombinant polypeptide encoded by a  
25       NOVX nucleic acid. Expression or activity of NOVX polypeptide is then measured in the test animal, as is expression or activity of the protein in a control animal which recombinantly-expresses NOVX polypeptide and is not at increased risk for the disorder or syndrome. Next, the expression of NOVX polypeptide in both the test animal and the control animal is compared. A change in the activity of NOVX polypeptide in the test animal relative to the  
30       control animal indicates the test compound is a modulator of latency of the disorder or syndrome.

      In yet another aspect, the invention includes a method for determining the presence of or predisposition to a disease associated with altered levels of a NOVX polypeptide, a NOVX nucleic acid, or both, in a subject (*e.g.*, a human subject). The method includes measuring the

amount of the NOVX polypeptide in a test sample from the subject and comparing the amount of the polypeptide in the test sample to the amount of the NOVX polypeptide present in a control sample. An alteration in the level of the NOVX polypeptide in the test sample as compared to the control sample indicates the presence of or predisposition to a disease in the subject. Preferably, the predisposition includes, *e.g.*, the diseases and disorders disclosed above and/or other pathologies and disorders of the like. Also, the expression levels of the new polypeptides of the invention can be used in a method to screen for various cancers as well as to determine the stage of cancers.

In a further aspect, the invention includes a method of treating or preventing a pathological condition associated with a disorder in a mammal by administering to the subject a NOVX polypeptide, a NOVX nucleic acid, or a NOVX-specific antibody to a subject (*e.g.*, a human subject), in an amount sufficient to alleviate or prevent the pathological condition. In preferred embodiments, the disorder, includes, *e.g.*, the diseases and disorders disclosed above and/or other pathologies and disorders of the like.

In yet another aspect, the invention can be used in a method to identify the cellular receptors and downstream effectors of the invention by any one of a number of techniques commonly employed in the art. These include but are not limited to the two-hybrid system, affinity purification, co-precipitation with antibodies or other specific-interacting molecules.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Although methods and materials similar or equivalent to those described herein can be used in the practice or testing of the present invention, suitable methods and materials are described below. All publications, patent applications, patents, and other references mentioned herein are incorporated by reference in their entirety. In the case of conflict, the present specification, including definitions, will control. In addition, the materials, methods, and examples are illustrative only and not intended to be limiting.

Other features and advantages of the invention will be apparent from the following detailed description and claims.

30

## DETAILED DESCRIPTION OF THE INVENTION

The present invention provides novel nucleotides and polypeptides encoded thereby. Included in the invention are the novel nucleic acid sequences and their encoded polypeptides. The sequences are collectively referred to herein as "NOVX nucleic acids" or "NOVX

polynucleotides" and the corresponding encoded polypeptides are referred to as "NOVX polypeptides" or "NOVX proteins." Unless indicated otherwise, "NOVX" is meant to refer to any of the novel sequences disclosed herein. Table A provides a summary of the NOVX nucleic acids and their encoded polypeptides.

5

**TABLE A. Sequences and Corresponding SEQ ID Numbers**

NOVX Assignment	Internal Identification	SEQ ID NO (nucleic acid)	SEQ ID NO (polypeptide)	Homology
1a	CG56592-01	1	2	Claudin 6-like
1b	CG56586-01	3	4	Claudin-3-like
1c	CG56592-03	5	6	Claudin-6-like
1d	CG56592-02	7	8	Claudin 6-like
2	CG56596-01	9	10	Protein Serine Kinase -like
3a	CG56594-01	11	12	Claudin-19-like
3b	CG56594-02	13	14	Claudin-19-like
3c	CG57576-01	15	16	Claudin-19-like
4a	CG56589-01	17	18	Claudin-6-like
4b	CG56589-01	19	20	Claudin-6-like
4c	CG56589-02	21	22	Claudin-6-like
5a	CG56635-01	23	24	Monocarboxylate transporter (MCT3)-like
5b	CG56635-02	25	26	Monocarboxylate transporter 3-like
5c	CG56635-03	27	28	Monocarboxylate transporter 3-like
5d	CG56635-04	29	30	Monocarboxylate transporter 3-like
5e	CG56635-05	31	32	Monocarboxylate transporter 3-like
6	CG56674-01	33	34	Nitrilase-1-like
7a	CG56613-01	35	36	Cleavage Signal-1 Protein-Like
7b	CG56613-02	37	38	Cleavage Signal-1 Protein-Like
7c	CG56613-03	39	40	Cleavage Signal-1 Protein-Like
7d	174307820	41	42	Cleavage Signal-1 Protein-Like
7e	167474749	323	324	Cleavage Signal-1 Protein-Like
8	153472451	43	44	Matriptase -like
9a	CG56554-01	45	46	Neuropeptide Y/Peptide YY receptor -like
9b	CG56554-02	47	48	Neuropeptide Y/Peptide YY receptor -like
10	CG55964-01	49	50	G-Protein Coupled Receptor-like
11	CG55966-01	51	52	G-Protein Coupled Receptor-like
12	CG56003-01	53	54	Neuromodulin-like
13a	CG56021-01	55	56	G-Protein Coupled Receptor-like
13b	CG56021-02	57	58	G-Protein Coupled Receptor-like
14	CG56023-01	59	60	G-Protein Coupled Receptor-like
15a	CG56065-01	61	62	G-Protein Coupled Receptor-

				like
15b	CG56065-02	63	64	G-Protein Coupled Receptor-like
16a	CG56067-01	65	66	G-Protein Coupled Receptor-like
16b	CG56753-02	67	68	G-Protein Coupled Receptor-like
17a	CG56657-01	69	70	G-Protein Coupled Receptor-like
17b	CG56657-02	71	72	G-Protein Coupled Receptor-like
17c	CG56659-01	73	74	G-Protein Coupled Receptor-like
17d	CG56659_02	75	76	G-Protein Coupled Receptor-like
18a	CG56663-01	77	78	G-Protein Coupled Receptor-like
18b	CG56663-02	79	80	G-Protein Coupled Receptor-like
19a	CG56665-01	81	82	G-Protein Coupled Receptor-like
19b	CG56665-02	83	84	G-Protein Coupled Receptor-like
20	CG56667-01	85	86	G-Protein Coupled Receptor-like
21a	CG56639-01	87	88	Adrenal Secretory Serine Protease-Like
21b	CG56639-02	89	90	Adrenal Secretory Serine Protease-Like
22a	CG56643-01	91	92	Adrenal Secretory Serine Protease-Like
22b	CG56643-02	93	94	Adrenal Secretory Serine Protease-Like
22c	CG56643-03	95	96	Adrenal Secretory Serine Protease-Like
23a	CG56647-02	97	98	Serine Protease DESC1-like
23b	CG56647-03	99	100	Serine Protease DESC1-like
23c	CG56647-01	101	102	Serine Protease DESC1-like

97d	CG57070-04	313	314	Carboxypeptidase A1-like
97e	CG57070-05	315	316	Carboxypeptidase A1-like
97f	CG57070-06	317	318	Carboxypeptidase A1-like
98	CG56939-01	319	320	Agrin-like
99	CG57010-01	321	322	SNC73-like

NOVX nucleic acids and their encoded polypeptides are useful in a variety of applications and contexts. The various NOVX nucleic acids and polypeptides according to the invention are useful as novel members of the protein families according to the presence of domains and sequence relatedness to previously described proteins. Additionally, NOVX nucleic acids and polypeptides can also be used to identify proteins that are members of the family to which the NOVX polypeptides belong.

NOV1, NOV3, and NOV4 are homologous to a Claudin-like family of proteins. Thus, the NOV1, NOV3, and NOV4 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions.

NOV2 is homologous to the Protein Serine Kinase-like family of proteins. Thus NOV2 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions.

NOV5 is homologous to a family of Monocarboxylate transporter-like proteins. Thus, the NOV5 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV6 is homologous to the nitrilase-1-like family of proteins. Thus, NOV6 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions.

NOV7 is homologous to the Cleavage Signal-1-like family of proteins. Thus NOV7 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions.

NOV8 is homologous to the Matripase-like family of proteins. Thus NOV8 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in, various pathologies or conditions.

NOV9 is homologous to members of the Neuropeptide Y/Peptide YY receptor-like family of proteins. Thus, the NOV9 nucleic acids, polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions.

5       NOVs10 through 20, , NOV43, NOV44, and NOV83 are homologous to the G-Protein Coupled Receptor-like family of proteins. Thus, these nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions.

10       NOV21 and NOV22 are homologous to the Adrenal; secretory serine protease like growth factor binding protein-like family of proteins. Thus, NOV21 and NOV22 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions.

15       NOV23 is homologous to the Serine Protease DESC-1-like family of proteins. Thus, NOV23 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in various pathologies or conditions.

NOV24 is homologous to the Parchorin-like family of proteins. Thus, NOV24 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or disorders.

20       NOV25 is homologous to the Protein Phosphatase-like family of proteins. Thus, NOV25 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions.

25       NOV26 is homologous to the GAGE7-like family of proteins. Thus, NOV26 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies/disorders.

30       NOV27 is homologous to the Sodium-Glucose Cotransporter-like family of proteins. Thus, NOV27 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV28 is homologous to the MYD-1-like family of proteins. Thus, NOV28 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV29 is homologous to the CRAL-TRIO-like family of proteins. Thus, NOV27 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

5 NOV30 is homologous to the Ryudocan-like family of proteins. Thus, NOV30 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV31 is homologous to the Sulfur-rich Keratin-like family of proteins. Thus,  
10 NOV31 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV32 is homologous to the DMNT1 associated protein-like family of proteins. Thus, NOV32 nucleic acids and polypeptides, antibodies and related compounds according to  
15 the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV33 is homologous to the Notch1-like family of proteins. Thus, NOV33 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or  
20 conditions

NOV34, NOV35, NOV51, NOV66, and NOV67 are homologous to the Olfactory Receptor-like family of proteins. Thus, NOV34, NOV35, NOV51, NOV66, and NOV67 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or  
25 conditions

NOV36 is homologous to the Cadherin 11-like family of proteins. Thus, NOV36 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

30 NOV37 is homologous to the Ten-M2-like family of proteins. Thus, NOV33 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV38 and NOV39 are homologous to the Activin/Inhibin-like family of proteins. Thus, NOV38 and NOV39 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

5 NOV40 is homologous to the UDP Glycosyltransferase-like family of proteins. Thus, NOV40 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV41 is homologous to the Sodium/Hydrogen Exchanger 4-like family of proteins. 10 Thus, NOV41 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV42 is homologous to the Kupffer Cell Receptor-like family of proteins. Thus, NOV42 nucleic acids and polypeptides, antibodies and related compounds according to the 15 invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV45 and NOV46 is homologous to the Mas Proto-Oncogene-like family of proteins. Thus, NOV45 and NOV46 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications 20 implicated in various pathologies or conditions

NOV47 is homologous to the Peptidyl-Prolyl Cis-Trans Isomerase-like family of proteins. Thus, NOV47 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

25 NOV48 is homologous to the Phospholipase C Delta-4-like family of proteins. Thus, NOV48 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV49 is homologous to the Leukotriene-B4 Omega Hydroxylase-like family of 30 proteins. Thus, NOV49 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV50 is homologous to the Protein Arginine N-Methyltransferase 2-like family of proteins. Thus, NOV50 nucleic acids and polypeptides, antibodies and related compounds

according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV52 is homologous to the H326-like family of proteins. Thus, NOV52 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be  
5 useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV53 is homologous to the Uracil Phosphoribosyltransferase-like family of proteins. Thus, NOV53 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various  
10 pathologies or conditions

NOV54 is homologous to the Protein Phosphatase 2C-like family of proteins. Thus, NOV54 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV55 is homologous to the Heparan Sulfate 6-Sulfotransferase 3-like family of proteins. Thus, NOV55 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV56 is homologous to the N-Hydroxyarylamine Sulfotransferase 3-like family of proteins. Thus, NOV56 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV57 is homologous to the Testis Specific Serine Kinase-3-like family of proteins. Thus, NOV57 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV58 is homologous to the Gap Junction Beta-5-like family of proteins. Thus, NOV58 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various  
30 pathologies or conditions

NOV59 is homologous to the Translation Initiation Factor 5-like family of proteins. Thus, NOV59 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV60 is homologous to the Lynx1-like family of proteins. Thus, NOV60 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

5 NOV61 is homologous to the Adlican-like family of proteins. Thus, NOV61 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

10 NOV62 is homologous to the Neuropsin Precursor-like family of proteins. Thus, NOV62 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

15 NOV63 is homologous to the Wnt-14-like family of proteins. Thus, NOV63 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

20 NOV64 is homologous to the Dipeptidyl peptidase-like family of proteins. Thus, NOV64 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV65 is homologous to the Protein phosphatase-like family of proteins. Thus, NOV65 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

25 NOV68 is homologous to the Endoglin (CD105 antigen)-like family of proteins. Thus, NOV68 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

30 NOV69 is homologous to the Interleukin 1 Epsilon-like family of proteins. Thus, NOV69 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV70 is homologous to the OS-9-like family of proteins. Thus, NOV70 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be

useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV71 is homologous to the Sodium/Hydrogen Exchanger 6-like family of proteins. Thus, NOV71 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV72 is homologous to the Ubiquitin Specific Protease-like family of proteins. Thus, NOV72 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV73 is homologous to the Sulfotransferase-like family of proteins. Thus, NOV73 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV74, NOV75, NOV76, NOV77, NOV78, NOV79, and NOV80 are homologous to the Dual Specificity Phosphatase-like family of proteins. Thus, NOV74, NOV75, NOV76, NOV77, NOV78, NOV79, and NOV80 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV81 is homologous to the Beta-1, 3-Galactosyltransferase-like family of proteins. Thus, NOV81 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV82 is homologous to the Peptide YY-like family of proteins. Thus, NOV82 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV84 is homologous to the Phospholipase C delta 1-like family of proteins. Thus, NOV84 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV85, NOV86, and NOV87 are homologous to the GTPase-Activating Protein-like family of proteins. Thus, NOV85, NOV86, and NOV87 nucleic acids and polypeptides,

antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV88 and NOV89 are homologous to the Glycerol-3-Phosphate Dehydrogenase-like family of proteins. Thus, NOV88 and NOV89 nucleic acids and polypeptides, antibodies  
5 and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV90 is homologous to the Serine/Threonine-Protein Kinase PAK 2-like family of proteins. Thus, NOV90 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated  
10 in various pathologies or conditions

NOV91 is homologous to the D-Dopachrome Tautomerase family of proteins. Thus, NOV91 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV92 is homologous to the Secreted leucine-rich repeat (LRR)-like family of proteins. Thus, NOV92 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated  
15 in various pathologies or conditions

NOV93 is homologous to the Inosine-5'-Monophosphate Dehydrogenase-like family of proteins. Thus, NOV93 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated  
20 in various pathologies or conditions

NOV94 is homologous to the Male-Specific Lethal 3-like family of proteins. Thus, NOV94 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various  
25 pathologies or conditions

NOV95 is homologous to the Cysteine Conjugate Beta Lyase-like family of proteins. Thus, NOV95 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various  
30 pathologies or conditions

NOV96 is homologous to the Monocarboxylate transporter-like family of proteins. Thus, NOV96 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

NOV97 is homologous to the Carboxypeptidase A1-like family of proteins. Thus, NOV97 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

5 NOV98 is homologous to the Agrin-like family of proteins. Thus, NOV98 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

10 NOV99 is homologous to the SNC73-like family of proteins. Thus, NOV99 nucleic acids and polypeptides, antibodies and related compounds according to the invention will be useful in therapeutic and diagnostic applications implicated in various pathologies or conditions

The NOVX nucleic acids and polypeptides can also be used to screen for molecules, which inhibit or enhance NOVX activity or function. Specifically, the nucleic acids and polypeptides according to the invention may be used as targets for the identification of small molecules that modulate or inhibit, *e.g.*, neurogenesis, cell differentiation, cell proliferation, hematopoiesis, wound healing and angiogenesis.

Additional utilities for the NOVX nucleic acids and polypeptides according to the invention are disclosed herein.

## 20 NOV1

NOV1 includes three novel human 1 Claudin-like proteins disclosed below. The disclosed sequences have been named NOV1a, NOV1b, NOV1c, NOV1d, NOV1e, NOV1f, and NOV1g.

## 25 NOV1a

A disclosed NOV1a nucleic acid of 687 nucleotides (also referred to as CG56592-02) encoding a novel human Claudin 6-like protein is shown in Table 1A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 6-8 and ending with a TAG termination codon at nucleotides 678-680. The start and stop codons are in bold letters in Table 1A, and the 5' and 3' untranslated regions are underlined.

**Table 1A. NOV1a nucleotide sequence (SEQ ID NO:1).**

```

In a search of public sequence databases, the NOV1a nucleic acid sequence, located on chromosome 12 has 337 of 534 bases (63%) identical to a gb:GENBANK-

ID:HSA249735|acc:AJ249735.1 mRNA from *Homo sapiens* (CLDN6 gene for claudin-6).

5 In all BLAST alignments herein, the "E-value" or "Expect" value is a numeric indication of the probability that the aligned sequences could have achieved their similarity to the BLAST query sequence by chance alone, within the database that was searched. For example, the probability that the subject ("Sbjct") retrieved from the NOV1a BLAST analysis, e.g., *Homo sapiens* CLDN6 gene for claudin-6, matched the Query NOV1a sequence purely  
10 by chance is  $1.4e^{-15}$ . The Expect value (E) is a parameter that describes the number of hits one can "expect" to see just by chance when searching a database of a particular size. It decreases exponentially with the Score (S) that is assigned to a match between two sequences. Essentially, the E value describes the random background noise that exists for matches between sequences.

15 The Expect value is used as a convenient way to create a significance threshold for reporting results. The default value used for blasting is typically set to 0.0001. In BLAST 2.0, the Expect value is also used instead of the P value (probability) to report the significance of matches. For example, an E value of one assigned to a hit can be interpreted as meaning that in a database of the current size one might expect to see one match with a similar score simply  
20 by chance. An E value of zero means that one would not expect to see any matches with a similar score simply by chance. See, e.g.,

<http://www.ncbi.nlm.nih.gov/Education/BLASTinfo/>. Occasionally, a string of X's or N's will result from a BLAST search. This is a result of automatic filtering of the query for low-complexity sequence that is performed to prevent artifactual hits. The filter substitutes any  
25 low-complexity sequence that it finds with the letter "N" in nucleotide sequence (e.g., "NNNNNNNNNNNNNNNN") or the letter "X" in protein sequences (e.g., "XXXXXXXXXX"). Low-complexity regions can result in high scores that reflect compositional bias rather than

significant position-by-position alignment. (Wootton and Federhen, Methods Enzymol 266:554-571, 1996).

The disclosed NOV1a polypeptide (SEQ ID NO:2) encoded by SEQ ID NO:1 has 229 amino acid residues and is presented in Table 1B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV1a has no signal peptide and is likely to be localized the plasma membrane with a certainty of 0.6400. Alternatively, NOV1a also may localize to the Golgi body with acertainty of 0.4600, the endoplasmic reticulum (membrane) with a certainty of 0.3700 or in the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for a NOV1a peptide is between amino acids 24 and 25, at: VCS-CV.

**Table 1B. Encoded NOV1a protein sequence (SEQ ID NO:2).**

--

A search of sequence databases reveals that the NOV1a amino acid sequence has 81 of 207 amino acid residues (39%) identical to, and 111 of 207 amino acid residues (53%) similar to, the 219 amino acid residue ptnr:SWISSPROT-ACC:Q9Z262 protein from *Mus musculus* (Mouse) (Claudin-6) ( $E = 2.7e^{-27}$ ).

NOV1a is predicted to be expressed in Bone Marrow, Brain, Liver, Placenta, and Lung.

## NOV1b

A disclosed NOV1b nucleic acid of 687 nucleotides (also referred to as CG56586-01) encoding a human Claudin-3-like protein is shown in Table 1C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 6-8 and ending with a TAG codon at nucleotides 678-680. Putative untranslated regions upstream from the initiation codon, and downstream from the termination codon, if any, are underlined in Table 1C. The start and stop codons are in bold letters.

```

In a search of public sequence databases, the NOV1b nucleic acid sequence, located on chromosome 11 is 338 of 534 bases (63%) identical to a gb:GENBANK-

ID:HSA249735|acc:AJ249735.1 mRNA from *Homo sapiens* (CLDN6 gene for claudin-6). (E =  $2.8e^{-16}$ ).

The disclosed NOV1b polypeptide (SEQ ID NO:4) encoded by SEQ ID NO:3 has 224 amino acid residues and is presented in Table 1D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV1b has a signal peptide and is likely to be localized in the plasma membrane with a certainty of 0.4600. Alternatively, NOV1b may also localize to the microbody (peroxisome) with a certainty of 0.3200, the endoplasmic reticulum (membrane) with a certainty of 0.1000 or in the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for a NOV1b peptide is between amino acids 24 and 25, at: VCS-CV.

LLPPHAKT

```

A search of sequence databases reveals that the NOV1b amino acid sequence has 50 of 149 amino acid residues (33%) identical to, and 83 of 149 amino acid residues (55%) similar to, the 219 amino acid residue ptnr:SWISSPROT-ACC:Q63400 protein from *Rattus norvegicus* (Rat) (Claudin-3 (Ventral Prostate.1 Protein) (RVP1)) (E = 0.0).

NOV1b is predicted to be expressed in Bone Marrow, Brain, Liver, Placenta, and Lung.

### NOV1c

A disclosed NOV1c nucleic acid of 642 nucleotides (also referred to as CG56592-03) encoding a novel Claudin-6-like protein is shown in Table 1E. An open reading frame was

identified beginning with a ATG initiation codon at nucleotides 6-8 and ending with a TAG codon at nucleotides 609-611. The start and stop codons are in bold letters, and the 5' and 3' untranslated regions are underlined.

5 The disclosed NOV1c nucleic acid sequence maps to chromosome 12 and has 144 of 220 bases (65%) identical to a gb:GENBANK-ID:HSA249735|acc:AJ249735.1 mRNA from *Homo sapiens* (CLDN6 gene for claudin-6) (E = 0.0).

A disclosed NOV1c protein (SEQ ID NO:6) encoded by SEQ ID NO:5 has 201 amino acid residues, and is presented using the one-letter code in Table 1F. Signal P, Psort and/or  
 10 Hydropathy results predict that NOV1c does have a signal peptide, and is likely to be localized to the plasma membrane with a certainty of 0.4600. In other embodiments NOV1c is also likely to be localized to the microbody (peroxisome) with a certainty of 0.2651, to endoplasmic reticulum (membrane) with a certainty of 0.1000, or to the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV1c is  
 15 between positions 24 and 25, (VCS-CV).

The disclosed NOV1c amino acid has 55 of 94 amino acid residues (58%) identical to, and 62 of 94 amino acid residues (65%) similar to, the 220 amino acid residue  
 20 ptr:SP TREMBL-ACC:Q9D7U6 protein from *Mus musculus* (Mouse) (2210404A22RIK Protein) (E= 3.1e<sup>-47</sup>).

In addition, NOV1c is predicted to be expressed in Bone Marrow, Brain, Liver, Placenta, and Lung.

NOV1d

A disclosed NOV1d nucleic acid of 726 nucleotides (also referred to as CG56592-02) encoding a novel Claudin 6-like protein is shown in Table 1G. An open reading frame was identified beginning with an ATG codon at nucleotides 6-8 and ending with a TAG codon at nucleotides 693-695. The start and stop codons are in bold letters and the 5' and 3' untranslated regions are underlined in Table 1G.

In a search of public sequence databases, the NOV1d nucleic acid sequence, located on chromosome 12 has 336 of 534 bases (62%) identical to a gb:GENBANK-

10 ID:HSA249735|acc:AJ249735.1 mRNA from *Homo sapiens* (CLDN6 gene for claudin-6) (E = 6.5e<sup>-16</sup>).

The disclosed NOV1d polypeptide (SEQ ID NO:8) encoded by SEQ ID NO:7 has 229 amino acid residues and is presented in Table 1H using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV1d has no signal peptide and is likely to be  
 15 localized to the plasma membrane with a certainty of 0.6400. Alternatively, NOV1d may also localize to the Golgi body with a certainty of 0.4600, the endoplasmic reticulum (membrane) with a certainty of 0.3700 or in the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for a NOV1d peptide is between amino acids 24 and 25, at: VCS-CV.

 SFHLMRLPRNLVI

A search of sequence databases reveals that the NOV1d amino acid sequence has 81 of 207 amino acid residues (39%) identical to, and 111 of 207 amino acid residues (53%) similar

to, the 219 amino acid residue ptrn:SWISSPROT-ACC:Q9Z262 protein from *Mus musculus* (Mouse) (Claudin-6) ( $E = 2.8e^{-27}$ ).

Expression information was derived from the tissue sources of the sequences that were included in the derivation of NOV1d. The sequence is predicted to be expressed in Bone Marrow, Brain, Liver, Placenta, and Lung.

Homologies to any of the above NOV1 proteins will be shared by the other NOV1 proteins insofar as they are homologous to each other as shown below. Any reference to NOV1 is assumed to refer to all four of the NOV1 proteins in general, unless otherwise noted.

The disclosed NOV1a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table II.

Table II. BLAST results for NOV1a

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 1J. In the ClustalW alignment of the NOV1 proteins, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and

can potentially be altered to a much broader extent without altering protein structure or function.

5

The claudins are a family of integral membrane proteins that are major components of tight junction (TJ) strands. When claudins are introduced into cells that lack tight junctions, networks of strands and grooves form at cell-cell contact sites that closely resemble native tight junctions. There are at least 17 members of this family in mammals. Claudin family members share ~38% amino acid identity, and are predicted to have four transmembrane (TM) domains, which is reminiscent of occludin, although they share no sequence similarity with it. Multiple sequence alignment reveals their sequences to be fairly well conserved in the first and fourth putative TM domains, and in the first and second extracellular loops, but they diverge in the second and third TM domains. Although the sequences of their C-terminal cytoplasmic domains vary, the known family members share a common motif of -Y-V. This has been postulated as a possible binding motif for PDZ domains of other tight junction-associated peripheral membrane proteins, such as ZO-1.

The disclosed NOV1 nucleic acid of the invention encoding a Human Claudin-like protein includes the nucleic acid whose sequence is provided in Table 1A, 1C, 1E, 1G, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 1A, 1C, 1E, or 1G while still encoding a protein that maintains its Human Claudin-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 37 percent of the bases may be so changed.

The disclosed NOV1 protein of the invention includes the Human Claudin-like protein whose sequence is provided in Table 1B, 1D, 1F, or 1H. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 1B, 1D, 1F, or 1H while still encoding a protein that maintains its Human

Claudin-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 66 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

5       The above disclosed information suggests that this Human Claudin-like protein (NOV1) is a member of a "Human Claudin family". Therefore, the NOV1 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small  
10   molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

      The NOV1 nucleic acids and proteins of the invention are useful in potential  
15   therapeutic applications implicated in cancer including but not limited to various pathologies and disorders as indicated below. For example, a cDNA encoding the Human Claudin-like protein (NOV1) may be useful in gene therapy, and the Human Claudin-like protein (NOV1) may be useful when administered to a subject in need thereof. By way of nonlimiting example, the compositions of the present invention will have efficacy for treatment of patients  
20   suffering from Von Hippel-Lindau (VHL) syndrome, Cirrhosis, Transplantation, Hemophilia, hypercoagulation, Idiopathic thrombocytopenic purpura, autoimmune disease, allergies, immunodeficiencies, transplantation, Graft versus host, Alzheimer's disease, Stroke, Tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-telangiectasia, Leukodystrophies,  
25   Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, Systemic lupus erythematosus, Autoimmune disease, Asthma, Emphysema, Scleroderma, allergy, and Cancer, or other pathologies or conditions. The NOV1 nucleic acid encoding the Human Claudin-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be  
30   assessed.

      NOV1 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV1 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies"

section below. The disclosed NOV1 proteins have multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

## 5 NOV2

A disclosed NOV2 nucleic acid of 1361 nucleotides (also referred to as CG56596-01) encoding a novel Protein Serine Kinase-like protein is shown in Table 2A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 20-22 and ending with a TAA codon at nucleotides 1268-1270. The start and stop codons are in bold letters in Table 2A.

**Table 2A. NOV2 nucleotide sequence (SEQ ID NO:9).**

The disclosed NOV2 nucleic acid sequence, localized to the q21.3-22 region of chromosome 18, has 685 of 997 bases (68%) identical to a gb:GENBANK-ID:HSA272212|acc:AJ272212.1 mRNA from *Homo sapiens* (mRNA for protein serine kinase (PSKH1 gene)) ( $E = 6.1e^{-85}$ ).

A NOV2 polypeptide (SEQ ID NO:10) encoded by SEQ ID NO:9 has 416 amino acid residues and is presented using the one-letter code in Table 2B. Signal P, Psort and/or Hydropathy results predict that NOV2 contains no signal peptide and is likely to be localized to the endoplasmic reticulum (membrane) with a certainty of 0.5500. Alternatively, NOV2 may also localize to the lysosome (lumen) with a certainty of 0.2403, the plasma membrane with a certainty of 0.1900, or the microbody (peroxisome) with a certainty of 0.1111.

**Table 2B. Encoded NOV2 protein sequence (SEQ ID NO:10).**

```

The disclosed NOV2 amino acid sequence has 267 of 412 amino acid residues (64%) identical to, and 332 of 412 amino acid residues (80%) similar to, the 424 amino acid residue ptmr:SPTREMBL-ACC:Q9NY19 protein from *Homo sapiens* (Human) (Protein Serine Kinase) ( $E = 1.1e^{-138}$ ).

NOV2 is predicted to be expressed in Kidney, Lymph node, Pancreas, Salivary Glands, Brain, and Placenta because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:HSA272212|acc:AJ272212.1) a closely related *Homo sapiens* mRNA for protein serine kinase (PSKH1 gene) homolog.

In addition, the sequence is predicted to be expressed in keratinocytes because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:HSPI13711|acc:AJ001696.2) a closely related *Homo sapiens* mRNA for hurpin, clone R7-1.1 homolog.

NOV2 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 2C.

**Table 2C. BLAST results for NOV2**

45				

The presence of identifiable domains in NOV2, as well as all other NOVX proteins, was determined by searches using software algorithms such as PROSITE, DOMAIN, Blocks, Pfam, ProDomain, and Prints, and then determining the Interpro number by crossing the domain match (or numbers) using the Interpro website (<http://www.ebi.ac.uk/interpro>). DOMAIN results for NOV2 as disclosed in Tables 2E-2G, were collected from the Conserved Domain Database (CDD) with Reverse Position Specific BLAST analyses. This BLAST analysis software samples domains found in the Smart and Pfam collections. For Table 2K and all successive DOMAIN sequence alignments, fully conserved single residues are indicated by black shading or by the sign (!) and "strong" semi-conserved residues are indicated by grey shading or by the sign (+). The "strong" group of conserved amino acid

residues may be any one of the following groups of amino acids: STA, NEQK, NHQK, NDEQ, QHRK, MILV, MILF, HY, FYW.

Tables 2E-G lists the domain description from DOMAIN analysis results against NOV2. This indicates that the NOV2 sequence has properties similar to those of other proteins known to contain this domain.

Protein phosphorylation is a fundamental process for the regulation of cellular functions. The coordinated action of both protein kinases and phosphatases controls the levels of phosphorylation and, hence, the activity of specific target proteins. One of the predominant roles of protein phosphorylation is in signal transduction, where extracellular signals are amplified and propagated by a cascade of protein phosphorylation and dephosphorylation events. Eukaryotic protein kinases are enzymes that belong to a very extensive family of proteins which share a conserved catalytic core common with both serine/threonine and tyrosine protein kinases. There are a number of conserved regions in the catalytic domain of protein kinases. In the N-terminal extremity of the catalytic domain there is a glycine-rich stretch of residues in the vicinity of a lysine residue, which has been shown to be involved in ATP binding. In the central part of the catalytic domain there is a conserved aspartic acid residue which is important for the catalytic activity of the enzyme.

The disclosed NOV2 nucleic acid of the invention encoding a Protein Serine Kinase-like protein includes the nucleic acid whose sequence is provided in Tables 2A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Tables 2A while still encoding a protein that maintains its Protein Serine Kinase-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include

chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense  
5 binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 32 percent of the bases may be so changed.

The disclosed NOV2 protein of the invention includes the Protein Serine Kinase -like protein whose sequence is provided in Tables 2B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown  
10 in Table 2B while still encoding a protein that maintains its Protein Serine Kinase-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 35 percent of the residues may be so changed.

The NOV2 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Diabetes, Von Hippel-Lindau (VHL) syndrome ,  
15 Pancreatitis, Obesity, Lymphedema , Allergies, Alzheimer's disease, Stroke, Tuberosclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-telangiectasia, Leukodystrophies, Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, Diabetes, Autoimmune disease, Renal artery stenosis, Interstitial nephritis, Glomerulonephritis, Polycystic kidney  
20 disease, Systemic lupus erythematosus, Renal tubular acidosis, IgA nephropathy, and/or other pathologies and disorders.

NOV2 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the  
25 art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV2 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which are useful in understanding of pathology of the disease and development of new drug targets for various disorders.

30

### NOV3

NOV3 includes three novel human Claudin-like proteins disclosed below. The disclosed sequences have been named NOV3a, NOV3b, and NOV3c.

**NOV3a**

A disclosed NOV3a nucleic acid of 695 nucleotides (designated CuraGen Acc. No. CG56594-01) encoding a novel Claudin-19-like protein is shown in Table 3A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 53-55 and ending with a TGA codon at nucleotides 662-664. A putative untranslated region downstream from the termination codon is underlined in Table 3A, and the start and stop codons are in bold letters.

**Table 3A. NOV3a Nucleotide Sequence (SEQ ID NO:11)**

TGGACCCTCTGCTGCTGCCCAGAGTACGTCTGAGCTCCGCCTGCCCTGGCCAGCCCCCACCCA

The nucleic acid sequence, localized to chromosome 1, has 402 of 482 bases (83%) identical to a gb:GENBANK-ID:AF249889|acc:AF249889.1 mRNA from *Mus musculus* (claudin-19 mRNA, partial cds) ( $E = 1.1e^{-67}$ ).

A NOV3a polypeptide (SEQ ID NO:12) encoded by SEQ ID NO:11 is 203 amino acid residues and is presented using the one letter code in Table 3B. Signal P, Psort and/or Hydropathy results predict that NOV3a has no signal peptide and is likely to be localized at the endoplasmic reticulum (membrane) with a certainty of 0.6850. Alternatively, NOV3a may also localize to the plasma membrane with a certainty of 0.6400, the Golgi body with a certainty of 0.4600, or the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV3a is between positions 23 and 24: IIA-ST.

**Table 3B. NOV3a protein sequence (SEQ ID NO:12)**

FNPEFGPALFVGWASAGLAVLGGSLCCTCPEPERPNSSPQPYRPGPSAAAREYV

The full amino acid sequence of the protein of the invention was found to have 174 of 193 amino acid residues (90%) identical to, and 178 of 193 amino acid residues (92%) similar to, the 193 amino acid residue ptmr:TREMBLNEW-ACC:AAF98323 protein from *Mus musculus* (Mouse) (CLAUDIN-19) ( $E = 5.7e^{-89}$ ).

NOV3a is predicted to be expressed in at least the Spinal cord.

### NOV3b

A disclosed NOV3b nucleic acid of 695 nucleotides (also referred to as CG56594-01) encoding a novel Claudin-19-like protein is shown in Table 3C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 53-55 and ending with a TGA termination codon at nucleotides 662-664. The start and stop codons are in bold letters in Table 3C, and the 5' and 3' untranslated regions are underlined.

**Table 3C. NOV3b nucleotide sequence (SEQ ID NO:13).**

CCGAGAGTACGTCTGAGCTCCGCCTGCCCTGGCCAGCCCCCACCCA
```

In a search of public sequence databases, the NOV3b nucleic acid sequence, located on chromosome 1 has 402 of 482 bases (83%) identical to a gb:GENBANK-ID:AF249889|acc:AF249889.1 mRNA from *Mus musculus* (claudin-19 mRNA, partial cds) (E = 1.1e<sup>-67</sup>).

The disclosed NOV3b polypeptide (SEQ ID NO:14) encoded by SEQ ID NO:13 has 203 amino acid residues and is presented in Table 3D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV3b has a signal peptide and is likely to be localized the endoplasmic reticulum (membrane) with a certainty of 0.6850. Alternatively, NOV3b may also localize to the plasma membrane with a certainty of 0.6400, the Golgi body with a certainty of 0.4600 or in the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV3b is between positions 23 and 24: IIA-ST.

**Table 3D. Encoded NOV3b protein sequence (SEQ ID NO:14).**

TQEFFNPEFGPALFVGWASAGLAVLGGSFLCTCPEPERPNSSFPYRPGPSAAAREYV
```

A search of sequence databases reveals that the NOV3b amino acid sequence has 174 of 193 amino acid residues (90%) identical to, and 178 of 193 amino acid residues (92%)

similar to, the 193 amino acid residue ptnr:TREMBLNEW-ACC:AAF98323 protein from *Mus musculus* (Mouse) (Claudin-19) ( $E = 5.7e^{-89}$ ).

NOV3b is predicted to be expressed in at least the Spinal cord.

#### NOV3c

- 5 A disclosed NOV3c nucleic acid of 690 nucleotides (also referred to as CG57576-01) encoding a novel Claudin 19-like protein is shown in Table 3E. An open reading frame was identified beginning with an ATG codon at nucleotides 51-53 and ending with a TGA codon at nucleotides 684-686. The start and stop codons are in bold letters and the 5' and 3' untranslated regions are underlined in Table 3I. Because the start codon is not a traditional
- 10 initiation codon, NOV3c could be a partial reading frame. NOV3c could extend further in the 5' direction.

**Table 3E. NOV3c nucleotide sequence (SEQ ID NO:15).**

```

- In a search of public sequence databases, the NOV3c nucleic acid sequence, located on
- 15 chromosome 1 has 445 of 671 bases (66%) identical to a gb:GENBANK-ID:HSA011497|acc:AJ011497.1 mRNA from *Homo sapiens* (mRNA for Claudin-7) ( $E = 5.3e^{-46}$ ).

- The disclosed NOV3c polypeptide (SEQ ID NO:16) encoded by SEQ ID NO:15 has 211 amino acid residues and is presented in Table 3F using the one-letter amino acid code.
- 20 Signal P, Psort and/or Hydropathy results predict that NOV3c has no signal peptide and is likely to be localized the the endoplasmic reticulum (membrane) with a certainty of 0.6850. Alternatively, NOV3c may also localize to the plasma membrane with acertainty of 0.6400, the Golgi body with a certainty of 0.4600 or in the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for a NOV3c peptide is between amino acids
- 25 23 and 24, at: IIA-ST.

**Table 3F. Encoded NOV3c protein sequence (SEQ ID NO:16).**

MANSGQLQLLGYFLALGGWVGIIASTALPQWKQSSYAGDAIITAVGLYEGLWMSQSTGQVQCKLYDSL

 TQEFFNPSTPVNARYEFGPALFVGWASAGLAVLGGFSLCCTCPEPERPNSSPQPYRPGPSAAAREYV

A search of sequence databases reveals that the NOV3c amino acid sequence has 121 of 211 amino acid residues (57%) identical to, and 159 of 211 amino acid residues (75%) similar to, the 211 amino acid residue ptnr:SWISSNEW-ACC:O95832 protein from *Homo sapiens* (Human) (Claudin-1 (Senescence-Associated Epithelial Membrane Protein)) ( $E = 9.6e^{-66}$ ).

NOV3c is predicted to be expressed in at least Spinal cord.

NOV3a also has homology to the amino acid sequences shown in the BLASTP data listed in Table 3G.

**Table 3G. BLAST results for NOV3a**

The claudins are a family of integral membrane proteins that are major components of tight junction (TJ) strands. When claudins are introduced into cells that lack tight junctions, networks of strands and grooves form at cell-cell contact sites that closely resemble native tight junctions. There are at least 17 members of this family in mammals. Claudin family members share ~38% amino acid identity, and are predicted to have four transmembrane (TM) domains, which is reminiscent of occludin, although they share no sequence similarity with it. Multiple sequence alignment reveals their sequences to be fairly well conserved in the first and fourth putative TM domains, and in the first and second extracellular loops, but they diverge in the second and third TM domains. Although the sequences of their C-terminal cytoplasmic domains vary, the known family members share a common motif of -Y-V. This has been postulated as a possible binding motif for PDZ domains of other tight junction-associated peripheral membrane proteins, such as ZO-1.

The disclosed NOV3 nucleic acid of the invention encoding a Claudin-19 -like protein includes the nucleic acid whose sequence is provided in Table 3A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 3A while still encoding a protein that maintains its Claudin-19 -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids

just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least  
5 in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 17 percent of the bases may be so changed.

The disclosed NOV3 protein of the invention includes the Claudin-19 -like protein  
10 whose sequence is provided in Table 3B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 3B while still encoding a protein that maintains its Claudin-19 -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 48 percent of the residues may be so changed.

15 The protein similarity information, expression pattern, and map location for the Claudin-19-like protein and nucleic acid (NOV3) disclosed herein suggest that this NOV3 protein may have important structural and/or physiological functions characteristic of the Claudin-19 family. Therefore, the NOV3 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications. These include serving as a specific  
20 or selective nucleic acid or protein diagnostic and/or prognostic marker, wherein the presence or amount of the nucleic acid or the protein are to be assessed, as well as potential therapeutic applications such as the following: (i) a protein therapeutic, (ii) a small molecule drug target, (iii) an antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), (iv) a nucleic acid useful in gene therapy (gene delivery/gene ablation), and (v) a composition  
25 promoting tissue regeneration in vitro and in vivo.

The NOV3 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from Von Hippel-Lindau (VHL) syndrome, Cirrhosis, Transplantation, Hemophilia,  
30 hypercoagulation, Idiopathic thrombocytopenic purpura, autoimmune disease, allergies, immunodeficiencies, transplantation, Graft versus host, Alzheimer's disease, Stroke, Tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-telangiectasia, Leukodystrophies, Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, Systemic lupus

erythematosus, Autoimmune disease, Asthma, Emphysema, Scleroderma, allergy, and Cancer, and/or other pathologies. The NOV3 nucleic acids, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed.

- 5 NOV3 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. These novel proteins can be used in assay systems for functional analysis of
- 10 various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV4

- NOV4 includes three novel human I Claudin-like proteins disclosed below. The
- 15 disclosed sequences have been named NOV4a, NOV4b, and NOV4c.

#### NOV4a

- A disclosed NOV4a nucleic acid of 694 nucleotides (also referred to as CG56589-01) encoding a novel Claudin-6-like protein is shown in Table 4A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 11-13 and ending with a
- 20 TAA codon at nucleotides 671-673. Putative untranslated regions upstream from the initiation codon and downstream from the termination codon are underlined in Table 4A, and the start and stop codons are in bold letters.

The NOV4a nucleic acid was identified on chromosome 4 and has 330 of 556 bases (59%) identical to a gb:GENBANK-ID:AF134160|acc:AF134160.1 mRNA from *Homo sapiens* (claudin-1 (CLDN1) mRNA, complete cds) ( $E = 2.9e^{-9}$ ).

A disclosed NOV4a polypeptide (SEQ ID NO:18) encoded by SEQ ID NO:17 is 220 amino acid residues and is presented using the one-letter code in Table 4B. Signal P, Psort and/or Hydropathy results predict that NOV4a has no signal peptide and is likely to be localized in the plasma membrane with a certainty of 0.6400. Alternatively, NOV4a may also localize to the Golgi body with a certainty of 0.4600, the endoplasmic reticulum (membrane) with a certainty of 0.3700, or the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV4a is between positions 24 and 25: ILS-II.

**Table 4B. Encoded NOV4a protein sequence (SEQ ID NO:18)**

---

The disclosed NOV4a amino acid sequence has 84 of 204 amino acid residues (41%) identical to, and 119 of 204 amino acid residues (58%) similar to, the 219 amino acid residue ptnr:SWISSPROT-ACC:Q9Z262 protein from *Mus musculus* (Mouse) (Claudin-6) ( $E = 1.1e^{-32}$ ).

NOV4a is predicted to be expressed in at least Brain. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, the sequence is predicted to be expressed in Adrenal Gland/Suprarenal gland, Brain, Bronchus, Brown adipose, Cervix, Colon, Coronary Artery, Epidermis, Gall Bladder, Heart, Hippocampus, Islets of Langerhans, Kidney, Liver, Lung, Lung Pleura, Mammary gland/Breast, Oesophagus, Ovary, Oviduct/Uterine Tube/Fallopian tube, Parotid Salivary glands, Peripheral Blood, Placenta, Prostate, Proximal Convolutd Tubule, Respiratory Bronchiole, Skin, Stomach, Substantia Nigra, Thymus, Thyroid, Trachea, Umbilical Vein, Uterus, and Vulva.

#### NOV4b

A disclosed NOV4b nucleic acid of 694 nucleotides (also referred to as CG56589-01) encoding a novel Claudin-6-like protein is shown in Table 4C. An open reading frame was identified beginning with an ATG codon at nucleotides 11-13 and ending with a TAA codon at

nucleotides 671-675. The start and stop codons are in bold letters and the 5' and 3' untranslated regions are underlined in Table 4C. Because the start codon is not a traditional initiation codon, NOV4b could be a partial reading frame. NOV4b could extend further in the 5' direction.

In a search of public sequence databases, the NOV4b nucleic acid sequence, located on chromosome 4 has 330 of 556 bases (59%) identical to a gb:GENBANK-

ID:AF134160|acc:AF134160.1 mRNA from *Homo sapiens* (claudin-1 (CLDN1) mRNA, complete cds) ( $E = 2.9e^{-09}$ ).

10

The disclosed NOV4b polypeptide (SEQ ID NO:20) encoded by SEQ ID NO:19 has 220 amino acid residues and is presented in Table 4D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV4b has no signal peptide and is likely to be localized the the plasma membrane with a certainty of 0.6400. Alternatively, NOV4b may also localize to the Golgi body with acertainty of 0.4600, the endoplasmic reticulum (membrane) with a certainty of 0.3700 or in the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for a NOV4b peptide is between amino acids 24 and 25, at: ILS-II.

15

20

A search of sequence databases reveals that the NOV4b amino acid sequence has 84 of 204 amino acid residues (41%) identical to, and 119 of 204 amino acid residues (58%) similar to, the 219 amino acid residue ptr:SWISSPROT-ACC:Q9Z262 protein from *Mus musculus* (Mouse) (Claudin-6) ( $E = 1.1e^{-32}$ ).

25

NOV4b is predicted to be expressed in at least Brain.

In addition, NOV4c is predicted to be expressed in Adrenal Gland/Suprarenal gland, Brain, Bronchus, Brown adipose, Cervix, Colon, Coronary Artery, Epidermis, Gall Bladder, Heart, Hippocampus, Islets of Langerhans, Kidney, Liver, Lung, Lung Pleura, Mammary gland/Breast, Oesophagus, Ovary, Oviduct/Uterine Tube/Fallopian tube, Parotid Salivary glands, Peripheral Blood, Placenta, Prostate, Proximal Convoluted Tubule, Respiratory Bronchiole, Skin, Stomach, Substantia Nigra, Thymus, Thyroid, Trachea, Umbilical Vein, Uterus, and Vulva.

#### NOV4c

A disclosed NOV4c nucleic acid of 694 nucleotides (also referred to as CG56589-02) encoding a novel Claudin 6-like protein is shown in Table 4E. An open reading frame was identified beginning with an ATG codon at nucleotides 11-13 and ending with a TAA codon at nucleotides 671-673. The start and stop codons are in bold letters and the 5' and 3' untranslated regions are underlined in Table 4E.

The claudins are a family of integral membrane proteins that are major components of tight junction (TJ) strands. When claudins are introduced into cells that lack tight junctions, networks of strands and grooves form at cell-cell contact sites that closely resemble native tight junctions. There are at least 17 members of this family in mammals. Claudin family members share ~38% amino acid identity, and are predicted to have four transmembrane (TM) domains, which is reminiscent of occludin, although they share no sequence similarity with it. Multiple sequence alignment reveals their sequences to be fairly well conserved in the first and fourth putative TM domains, and in the first and second extracellular loops, but they diverge in the second and third TM domains. Although the sequences of their C-terminal cytoplasmic domains vary, the known family members share a common motif of -Y-V. This has been postulated as a possible binding motif for PDZ domains of other tight junction-associated peripheral membrane proteins, such as ZO-1.

The disclosed NOV4 nucleic acid of the invention encoding a Claudin-6 -like protein includes the nucleic acid whose sequence is provided in Table 4A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 4A while still encoding a protein that maintains its Claudin-6 -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or

complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 41 percent of the bases may be so changed.

The disclosed NOV4 protein of the invention includes the Claudin-6 -like protein whose sequence is provided in Table 4B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 4B while still encoding a protein that maintains its Claudin-6-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 61 percent of the residues may be so changed.

The NOV4 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Von Hippel-Lindau (VHL) syndrome, Cirrhosis, Transplantation, Hemophilia, hypercoagulation, Idiopathic thrombocytopenic purpura, autoimmune disease, allergies, immunodeficiencies, transplantation, Graft versus host, Alzheimer's disease, Stroke, Tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-telangiectasia, Leukodystrophies, Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, Systemic lupus erythematosus, Autoimmune disease, Asthma, Emphysema, Scleroderma, allergy, and Cancer, and/or other pathologies and disorders of the like. The NOV4 nucleic acid, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed.

NOV4 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV4 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

## NOV5

NOV5 includes three novel Monocarboxylate transporter (MCT3)-like proteins disclosed below. The disclosed sequences have been named NOV5a, NOV5b, NOV5c, NOV5d, and NOV5e.

### NOV5a

A disclosed NOV5a nucleic acid of 1502 nucleotides (also referred to as CG56635-01) encoding a novel Monocarboxylate transporter (MCT3)-like protein is shown in Table 5a. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 24-26 and ending with a TGA codon at nucleotides 1365-1367. The start and stop codons are in bold letters in Table 5A.

The disclosed NOV5a nucleic acid sequence, located on chromosome 17, has 672 of 1110 bases (60%) identical to a gb:GENBANK-ID:AF132610|acc:AF132610.1 mRNA from *Homo sapiens* (monocarboxylate transporter MCT3 mRNA, complete cds) ( $E = 1.6e^{-29}$ ).

A disclosed NOV5a polypeptide (SEQ ID NO:24) encoded by SEQ ID NO:23 is 447 amino acid residues and is presented using the one-letter amino acid code in Table 5B. Signal P, Psort and/or Hydropathy results predict that NOV5a contains no signal peptide and is likely to be localized in the endoplasmic reticulum (membrane) with a certainty of 0.6850.

Alternatively, NOV5a is also likely to be localized to the plasma membrane with a certainty of

0.6400, to the Golgi body with a certainty of 0.4600, or to the endoplasmic reticulum (lumen) with a certainty of 0.1000

5 The disclosed NOV5a amino acid sequence has 96 of 198 amino acid residues (48%) identical to, and 122 of 198 amino acid residues (61%) similar to, the 504 amino acid residue ptnr:SPTREMBL-ACC:O95907 protein from *Homo sapiens* (Human) (DJ1039K5.2 (Similar To Monocarboxylate Transporter (MCT3))) ( $E = 1.2e^{-67}$ ).

10 NOV5a is predicted to be expressed in at least Adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain - whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, retina, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus.

#### NOV5b

15 A disclosed NOV5b nucleic acid of 611 nucleotides (also referred to as CG56635-02) encoding a novel Monocarboxylate transporter 3-like protein is shown in Table 5C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 6-8 and ending with a TGA codon at nucleotides 500-502. The start and stop codons are in bold letters in Table 5B.

10

The disclosed NOV5b amino acid sequence has 53 of 110 amino acid residues (48%) identical to, and 72 of 110 amino acid residues (65%) similar to, the 504 amino acid residue ptnr:SPTREMBL-ACC:Q9UBE2 protein from *Homo sapiens* (Human) (Monocarboxylate Transporter MCT3) ( $E = 2.9e^{-28}$ ).

- 15 NOV5b is predicted to be expressed in at least the following tissues: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain - whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid,  
20 trachea and uterus.

#### NOV5c

- A disclosed NOV5c nucleic acid of 704 nucleotides (also referred to as CG56635-03) encoding a novel Monocarboxylate transporter 3-like protein is shown in Table 5E. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 28-30 and  
25 ending with a TGA codon at nucleotides 673-675. The start and stop codons are in bold letters in Table 5E.

Monocarboxylates such as lactate and pyruvate play a central role in cellular metabolism and metabolic communication between tissues. Essential to these roles is their rapid transport across the plasma membrane, which is catalysed by a recently identified family of proton-linked monocarboxylate transporters (MCTs). Nine MCT-related sequences have so far been identified in mammals, each having a different tissue distribution, whereas six related proteins can be recognized in *Caenorhabditis elegans* and 4 in *Saccharomyces cerevisiae*. Direct demonstration of proton-linked lactate and pyruvate transport has been demonstrated for mammalian MCT1-MCT4, but only for MCT1 and MCT2 have detailed analyses of substrate and inhibitor kinetics been described following heterologous expression in *Xenopus* oocytes. MCT1 is ubiquitously expressed, but is especially prominent in heart and red muscle, where it is up-regulated in response to increased work, suggesting a special role in lactic acid oxidation. By contrast, MCT4 is most evident in white muscle and other cells with a high glycolytic rate, such as tumour cells and white blood cells, suggesting it is expressed where lactic acid efflux predominates. MCT2 has a ten-fold higher affinity for substrates than MCT1

and MCT4 and is found in cells where rapid uptake at low substrate concentrations may be required, including the proximal kidney tubules, neurons and sperm tails. MCT3 is uniquely expressed in the retinal pigment epithelium. MCT1 and MCT4 have been shown to interact specifically with OX-47 (CD147), a member of the immunoglobulin superfamily with a single  
5 transmembrane helix. This interaction appears to assist MCT expression at the cell surface

The disclosed NOV5 nucleic acid of the invention encoding a Monocarboxylate transporter (MCT3)-like protein includes the nucleic acid whose sequence is provided in Table 5A, 5C, 5E, 5G, 5I or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table  
10 5A, 5C, 5E, 5G, or 5I while still encoding a protein that maintains its Monocarboxylate transporter (MCT3)-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid  
15 fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic  
20 applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 40 percent of the bases may be so changed.

The disclosed NOV5 protein of the invention includes the Monocarboxylate transporter (MCT3)-like protein whose sequence is provided in Table 5B, 5D, 5F, 5H, or 5J. The invention also includes a mutant or variant protein any of whose residues may be changed  
25 from the corresponding residue shown in Table 5B, 5D, 5F, 5H, or 5J while still encoding a protein that maintains its Monocarboxylate transporter (MCT3)-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 67 percent of the residues may be so changed.

NOV5 nucleic acid and polypeptide show homology to the Monocarboxylate  
30 transporter (MCT3) family of proteins. Accordingly, to the NOV5 nucleic acid and polypeptide may function as members of this family. The NOV5 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this

invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The nucleic acids and proteins of NOV5 are useful in metabolic disorders such as salla disease, infantile sialic acid storage disease, symptomatic deficiency in lactate transport, subnormal erythrocyte lactate transport, muscle injuries, cystinosis, streptozotocin-induced diabetes, hypoxia, cardiac arrest or stroke, neuronal disorders, retinal angiogenesis, and/or other pathologies and disorders.

NOV5 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV5 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

## NOV6

A disclosed NOV6 nucleic acid of 1336 nucleotides (also referred to CG56674-01) encoding a novel Nitrilase-1-like protein is shown in Table 6A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 77-79 and ending with a TAA codon at nucleotides 1058-1060. In Table 6A, the 5' and 3' untranslated regions are underlined and the start and stop codons are in bold letters.

The disclosed NOV6 nucleic acid sequence, localized to the p14.2 region of  
 chromosome 3, has 1319 of 1329 bases (99%) identical to a gb:GENBANK-  
 ID:AF069987|acc:AF069987.1 mRNA from *Homo sapiens* (nitrilase 1 (NIT1) mRNA,  
 5 complete cds) ( $E = 3.1e^{-290}$ ).

A disclosed NOV6 polypeptide (SEQ ID NO:34) encoded by SEQ ID NO:33 is 327  
 amino acid residues and is presented using the one-letter amino acid code in Table 6B. Signal  
 P, Psort and/or Hydropathy results predict that NOV6 has a signal peptide and is likely to be  
 localized in the cytoplasm with a certainty of 0.4500. Alternatively, NOV6 is also likely to be  
 10 localized to the microbody (peroxisome) with a certainty of 0.3000, to the lysosome (lumen)  
 with a certainty of 0.2021, or to the mitochondrial matrix space with a certainty of 0.1000. The  
 most likely cleavage site for NOV6 is between positions 27 and 28: LSG-EG

5        The tumor suppressor gene FHIT encompasses the common human chromosomal fragile site at 3p14.2 and numerous cancer cell biallelic deletions. In human and mouse, the nitrilase homologs and Fhit are encoded by two different genes: FHIT and NIT1, localized on chromosomes 3 and 1 in human, and 14 and 1 in mouse, respectively.

10        Bacterial and plant nitrilases are enzymes that cleave nitriles and organic amides to the corresponding carboxylic acids plus ammonia. The NIT1 gene is expressed as alternatively spliced transcripts. The major NIT1 transcript encodes a deduced 327-amino acid protein that shares 90% amino acid sequence identity with mouse Nit1, 58% identity with the nitrilase domain of *C. elegans* NitFhit, and 53% identity with the nitrilase domain of *Drosophila* NitFhit. The NIT1 gene spans approximately 3.2 kb and contains 7 exons. Northern blot  
 15        analysis detected NIT1 transcripts of approximately 1.4 and 2.4 kb in all adult tissues examined, namely heart, brain, lung, liver, pancreas, kidney, skeletal muscle, and placenta. An approximately 1.2-kb NIT1 transcript was found in skeletal muscle and heart.

      The loss of Fhit expression in several common human cancers is well documented.

20        The disclosed NOV6 nucleic acid of the invention encoding a Nitrilase-1-like protein includes the nucleic acid whose sequence is provided in Table 6A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 6A while still encoding a protein that maintains its Nitrilase-1-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just  
 25        described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least  
 30        in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 1 percent of the bases may be so changed.

35        The disclosed NOV6 protein of the invention includes the Nitrilase-1-like protein whose sequence is provided in Table 6B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table

6B while still encoding a protein that maintains its Nitrilase-1-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 18 percent of the residues may be so changed.

5 The protein homology information, expression pattern, and map location for the Nitrilase-1-like protein and nucleic acid (NOV6) disclosed herein suggest that NOV6 may have important structural and/or physiological functions characteristic of the Nitrilase-1-like family. Therefore, the NOV6 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications. These include serving as a specific or selective nucleic acid or protein diagnostic and/or prognostic marker, wherein the presence or  
10 amount of the nucleic acid or the protein are to be assessed, as well as potential therapeutic applications such as the following: (i) a protein therapeutic, (ii) a small molecule drug target, (iii) an antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), (iv) a nucleic acid useful in gene therapy (gene delivery/gene ablation), and (v) a composition promoting tissue regeneration in vitro and in vivo.

15 The NOV6 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below and/or other pathologies. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from cancer, muscle conditions, disorders and diseases, longevity, and/or other pathologies/disorders. The NOV6 nucleic acid, or fragments  
20 thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed.

NOV6 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the  
25 art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV6 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug  
30 targets for various disorders.

## NOV7

NOV7 includes three novel cleavage signal-1 protein-like proteins disclosed below. The disclosed sequences have been named NOV7a, NOV7b, NOV7c, and NOV7d.

### NOV7a

5 A disclosed NOV7a nucleic acid of 1822 nucleotides (also referred to as CG56613-01) encoding a novel cleavage signal-1 protein-like protein is shown in Table 7A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 98-100 and ending with a TAA codon at nucleotides 839-841. A putative untranslated region upstream from the initiation codon is underlined in Table 7A. The start and stop codons are in  
10 bold letters.

15 The disclosed NOV7a nucleic acid sequence, localized to chromosome 2, has 1822 of 1828 bases (99%) identical to a gb:GENBANK-ID:HUMCS1PA|acc:M61199.1 mRNA from *Homo sapiens* (Human cleavage signal 1 protein mRNA, complete cds) (E = 0.0).

The disclosed NOV7a polypeptide (SEQ ID NO:36) encoded by SEQ ID NO:35 has 247 amino acid residues and is presented in Table 7B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV7a has a signal peptide and is likely to be localized to the cytoplasm with a certainty of 0.6500. Alternatively, NOV7A may also

localize to the mitochondrial matrix space with a certainty of 0.1000, or the lysosome (lumen) with a certainty of 0.1000.

**Table 7B. Encoded NOV7a protein sequence (SEQ ID NO:36).**

## 20 NOV7b

In the present invention, the target sequence identified previously, NOV7a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was  
25 examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on in silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely  
30 related human sequences sequences from other species. These primers were then employed in

PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain - whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated Accession Number NOV7b (6 aminoacid different from NOV7a) and NOV7c (2 aminoacid different from NOV7a).

A disclosed NOV7b nucleic acid of 806 nucleotides (also referred to as CG56613-02) encoding a novel cleavage signal-1 protein-like protein is shown in Table 7C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 21-23 and ending with a TAA codon at nucleotides 762-764. A putative untranslated region upstream from the initiation codon is underlined in Table 7C. The start and stop codons are in bold letters, and the 5' and 3' untranslated regions, if any, are underlined.

The disclosed NOV7b nucleic acid sequence, localized to chromosome 2, has 801 of 812 bases (98%) identical to a gb:GENBANK-ID:HUMCS1PA|acc:M61199.1 mRNA from *Homo sapiens* (Human cleavage signal 1 protein mRNA, complete cds) ( $E = 7.6e^{-171}$ ).

The disclosed NOV7b polypeptide (SEQ ID NO:38) encoded by SEQ ID NO:37 has 247 amino acid residues and is presented in Table 7D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV7b has no signal peptide and is

likely to be localized to the cytoplasm with a certainty of 0.6500. Alternatively, NOV7b may also localize to the mitochondrial matrix space with a certainty of 0.1000, or the lysosome (lumen) with a certainty of 0.1000.

**Table 7D. Encoded NOV7b protein sequence (SEQ ID NO:38).**

---

A search of sequence databases reveals that the NOV7b amino acid sequence has 240 of 249 amino acid residues (96%) identical to, and 242 of 249 amino acid residues (97%) similar to, the 249 amino acid residue ptnr:SWISSNEW-ACC:P28290 protein from *Homo sapiens* (Human) (Sperm-Specific Antigen 2 (Cleavage Signal-1 Protein) (CS-1)) (E = 9.7e<sup>-121</sup>).

NOV7b is predicted to be expressed in at least adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus, Aorta, Ascending Colon, Bone, Cervix, Cochlea, Colon, Dermis, Gall Bladder, Hypothalamus, Islets of Langerhans, Liver, Lung, Lymphoid tissue, Ovary, Parathyroid Gland, Parotid Salivary glands, Pineal Gland, Retina, Right Cerebellum, Skin, Tonsils, Umbilical Vein, Vein, Whole Organism. .

#### NOV7c

A disclosed NOV7c nucleic acid of 806 nucleotides (also referred to as CG56613-03) encoding a novel cleavage signal-1 protein-like protein is shown in Table 7E. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 21-23 and ending with a TAA codon at nucleotides 762-764. A putative untranslated region upstream from the initiation codon is underlined in Table 7E. The start and stop codons are in bold letters, and the 5' and 3' untranslated regions, if any, are underlined.

The disclosed NOV7c nucleic acid sequence, localized to chromosome 2, has 803 of 812 bases (98%) identical to a gb:GENBANK-ID:HUMCS1PA|acc:M61199.1 mRNA from *Homo sapiens* (Human cleavage signal 1 protein mRNA, complete cds) ( $E = 1.2e^{-171}$ ).

5 The disclosed NOV7c polypeptide (SEQ ID NO:40) encoded by SEQ ID NO:39 has 247 amino acid residues and is presented in Table 7F using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV7c has no signal peptide and is likely to be localized to the cytoplasm with a certainty of 0.6500. Alternatively, NOV7f may also localize to the mitochondrial matrix space with a certainty of 0.1000, or the lysosome  
10 (lumen) with a certainty of 0.1000.

**Table 7F. Encoded NOV7c protein sequence (SEQ ID NO:40).**

```

A search of sequence databases reveals that the NOV7c amino acid sequence has 242 of 249 amino acid residues (97%) identical to, and 244 of 249 amino acid residues (97%) similar to, the 249 amino acid residue ptnr:SWISSNEW-ACC:P28290 protein from *Homo sapiens* (Human) (Sperm-Specific Antigen 2 (Cleavage Signal-1 Protein) (CS-1)) ( $E = 1.4e^{-121}$ ).

NOV7c is predicted to be expressed in at least adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain - whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus, Aorta, Ascending Colon, Bone, Cervix, Cochlea, Colon, Dermis, Gall Bladder, Hypothalamus, Islets of

Langerhans, Liver, Lung, Lymphoid tissue, Ovary, Parathyroid Gland, Parotid Salivary glands, Pineal Gland, Retina, Right Cerebellum, Skin, Tonsils, Umbilical Vein, Vein, Whole Organism. .

#### NOV7d

- 5 A disclosed NOV7d nucleic acid of 705 nucleotides (also referred to as 174307820) encoding a novel cleavage signal-1 protein-like protein is shown in Table 7G. An open reading frame was identified beginning with an AGA initiation codon at nucleotides 1-3 and ending with nucleotides 703-705. The start codon is in bold letters, and the 5' and 3' untranslated regions, if any, are underlined. Because the start codon is not a traditional
- 10 initiation codon, and there is no stop codon, NOV7d could be a partial open reading frame extending further in the 5' and 3' directions.

**Table 7G. NOV7d nucleotide sequence (SEQ ID NO:41).**

#### NOV7e

- A disclosed NOV7e nucleic acid of 759 nucleotides (also referred to as 174307820) encoding a novel cleavage signal-1 protein-like protein is shown in Table 7I. An open reading frame was identified beginning with an AGA initiation codon at nucleotides 1-3 and ending with nucleotides 757-759. The start codon is in bold letters, and the 5' and 3' untranslated regions, if any, are underlined. Because the start codon is not a traditional initiation codon, and there is no stop codon, NOV7e could be a partial open reading frame extending further in the 5' and 3' directions.

The cleavage signal-1 protein (CS-1), a doublet antigen comprised of approximately 14-kDa and 18-kDa proteins has been shown to be present on the surface of sperm of various mammalian species including humans. Polyclonal antibodies to CS-1 inhibit the early cleavage of fertilized eggs without apparently affecting sperm penetration and pronuclear formation. The human CS-1 cDNA has been cloned and expressed in vitro to obtain the recombinant protein (reCS-1) molecule. The CS-1 cDNA clone has been isolated by immunological screening of a human testis lambda gt11 cDNA library with mono-specific polyclonal antibody against CS-1. The cDNA is 1828 bp long; the start codon assigned to the first ATG (bp 98-100) encodes a protein with 249 amino acid residues terminating at TAA (bp 845-847).

XCS-1 is a maternally expressed gene product that is the *Xenopus* homologue of the human cleavage signal protein (CS-1). XCS-1 may play an important role in regulating mitosis during early embryogenesis in *Xenopus laevis*. XCS-1 transcripts have been detected in oocytes. During development the XCS-1 protein has been detected on the membrane and in

the nucleus of blastomeres. It has also been detected on the mitotic spindle in mitotic cells and on the centrosomes in interphase cells. Overexpression of myc-XCS-1 in *Xenopus* embryos results in abnormal mitoses with increased numbers of centrosomes, multipolar spindles, and abnormal distribution of chromosomes. Incomplete cytokinesis resulting in multiple nuclei  
5 residing in the same cytoplasm with the daughter nuclei in different phases of the cell cycle has been observed. The phenotype depended on the presence of the N terminus of XCS-1 (aa 1-73) and a consensus NIMA kinase phosphorylation site (aa159-167). Mutations in this site affect the ability of the overexpressed XCS-1 protein to produce the phenotype.

The disclosed NOV7 nucleic acid of the invention encoding a Cleavage signal-1  
10 protein-like protein includes the nucleic acid whose sequence is provided in Table 7A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 7A while still encoding a protein that maintains its Cleavage signal-1 protein-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose  
15 sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or  
20 derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 1 percent of the bases may be so changed.

The disclosed NOV7 protein of the invention includes the Cleavage signal-1 protein-  
25 like protein whose sequence is provided in Table 7B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 2 while still encoding a protein that maintains its Cleavage signal-1 protein-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 21 percent of the residues may be so changed.

30 The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Cleavage signal-1 protein-like protein (NOV7) is a member of a "Cleavage signal-1 protein family". Therefore, the NOV7 nucleic acids and proteins identified here may be useful in potential therapeutic applications

implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene  
 5 delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV7 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in regulation of the cell cycle during early embryogenesis, and therefore may have potential application in the management of embryonic defects.  
 10 Additionally, this antigen may also be involved in human immunoinfertility and therefore may have application in the treatment of infertility, and/or other diseases or pathologies.

NOV7 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV7 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the  
 15 art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV7 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

20

## NOV8

A disclosed NOV8 nucleic acid of 2838 nucleotides (also referred to as 153472451) encoding a novel Matriptase-like protein is shown in Table 8A. An open reading frame was identified beginning with an TAG initiation codon at nucleotides 8-10 and ending with a TGA  
 25 codon at nucleotides 2279-2281. The start and stop codons are in bold letters in Table 8A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 8A. NOV8 nucleotide sequence (SEQ ID NO:43).**

The disclosed NOV8 nucleic acid sequence has 2644 of 2678 bases (98%) identical to a gb:GENBANK-ID:AF118224|acc:AF118224.2 mRNA from *Homo sapiens* (matriptase mRNA, complete cds) (E = 0.0).

- 5 The disclosed NOV8 polypeptide (SEQ ID NO:44) encoded by SEQ ID NO:43 has 757 amino acid residues is presented in Table 8B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV8 has a signal peptide and is likely to be localized in the plasma membrane with a certainty of 0.8110. Alternatively, NOV8 is predicted to be localized to the Golgi body with a certainty of 0.3000, to the endoplasmic reticulum (membrane) with a certainty of 0.2000, or to the microbody (peroxisome) with a certainty of 0.1527. The most likely cleavage site for NOV8 is between positions 8 and 9, ARK-GG.
- 10

A BLASTX of NOV8 shows that it has 699 of 729 amino acid residues (95%) identical to, and 702 of 729 amino acid residues (96%) similar to, the 855 amino acid residue ptnr:SPTREMBL-ACC:Q9Y5Y6 protein from *Homo sapiens* (Human) (Matriptase) (E = 0.0).

- 5 NOV8 is predicted to be expressed in at least the following tissues: Adrenal Gland/Suprarenal gland, Aorta, Ascending Colon, Bone Marrow, Brain, Bronchus, Cartilage, Colon, Duodenum, Gall Bladder, Heart, Islets of Langerhans, Kidney, Kidney Cortex, Lung, Mammary gland/Breast, Ovary, Pancreas, Parathyroid Gland, Parotid Salivary glands, Peripheral Blood, Pituitary Gland, Placenta, Prostate, Small Intestine, Stomach,
- 10 Thymus, Thyroid, Tonsils, Uterus, Vulva, Whole Organism.

In addition, NOV8 is predicted to be expressed in breast cancer, according to NOV8 nucleic acids, polypeptides, and antibodies. Accordingly to the invention will have diagnostic and therapeutic applications for the detection of breast cancer.

- The disclosed NOV8 polypeptide has homology to the amino acid sequences shown in
- 15 the BLASTP data listed in Table 8C.

Table 8C. BLAST results for NOV8

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 8D. In the ClustalW alignment of the NOV8 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

20

The predicted sequence described here belongs to the leucine-rich repeat protein family. It is homologous to insulin like growth factor binding protein (IGFBP) and RP105, a novel B cell surface molecule. It contains five leucine-rich repeat domains. Leucine-rich repeats (LRRs) are relatively short motifs (22-28 residues in length) found in a variety of cytoplasmic, membrane and extracellular proteins (1). A common property of this protein family involves protein-protein interaction. Other functions of LRR-containing proteins

25

include, for example, binding to enzymes and vascular repair (1) . LRRs form elongated non-globular structures and are often flanked by cysteine rich domains. The circulating insulin-like growth factors (IGF-I and -II) occur largely as components of a 140kDa protein complex with IGF binding protein-3 and the acid-labile subunit (ALS). This ternary complex regulates the metabolic effects of the serum IGFs by limiting their access to tissue fluids.

Because of the presence of the Leucine rich repeat domains and the homology to the IGFBP and RP105, we anticipate that the novel sequence described here will have useful properties and functions similar to these genes.

The NOV8 nucleic acid and polypeptide contain structural motifs (i.e. leucine rich repeat domains) that are characteristics of proteins belonging to the leucine-rich repeat protein family. Accordingly, the various NOV8 nucleic acids and polypeptides of the invention are useful, inter alia, as novel members of this protein family.

The disclosed NOV8 nucleic acid of the invention encoding a Insulin like growth factor binding protein-like protein includes the nucleic acid whose sequence is provided in Table 8A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 8A while still encoding a protein that maintains its Insulin like growth factor binding protein-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acid, up to about 2 percent of the bases may be so changed.

The disclosed NOV8 protein of the invention includes the Insulin like growth factor binding protein-like protein whose sequence is provided in Table 8B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 8B while still encoding a protein that maintains its Insulin like growth factor binding protein-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 18 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Insulin like growth factor binding protein-like protein (NOV8) is a member of a "Insulin like growth factor binding protein family". Therefore, the NOV8 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV8 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in diabetes, obesity, Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, stroke, tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral disorders, addiction, anxiety, pain, neuroprotection, cirrhosis, transplantation, hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, autoimmune disease, allergies, immunodeficiencies, graft versus host disease (GVHD), lymphoedema, and other diseases, disorders and conditions of the like.

NOV8 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV8 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV8 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

## NOV9

NOV9 includes three novel Neuropeptide Y/Peptide YY receptor -like proteins disclosed below. The disclosed sequences have been named NOV9a, and NOV9b.

## NOV9a

A disclosed NOV9a nucleic acid of 2276 nucleotides (also referred to as CG56554-01) encoding a novel Neuropeptide Y/Peptide YY receptor -like protein is shown in Table 9A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 370-372 and ending with a TAA codon at nucleotides 1549-1551. A putative untranslated region upstream from the initiation codon and downstream from the termination codon is underlined in Table 9A. The start and stop codons are in bold letters.

In a search of public sequence databases, the NOV9a nucleic acid sequence, localized to chromosome 4, has 372 of 434 bases (85%) identical to a gb:GENBANK-ID:HSA400877|acc:AJ400877.1 mRNA from *Homo sapiens* (ASCL3 gene, CEGP1 gene, C11orf14 gene, C11orf15 gene, C11orf16 gene and C11orf17 gene) ( $E = 2.5e^{-61}$ ).

The disclosed NOV9a polypeptide (SEQ ID NO:46) encoded by SEQ ID NO:45 has 393 amino acid residues and is presented in Table 9B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV9a has no signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively, NOV9a may also localize to the Golgi body with a certainty of 0.4000, the endoplasmic

reticulum (membrane) with a certainty of 0.3000, or in the microbody (peroxisome) with a certainty of 0.3000. The most likely cleavage site for NOV9a is between positions 64 and 65: GNA-LV.

**Table 9B. Encoded NOV9a protein sequence (SEQ ID NO:46).**

5

A search of sequence databases reveals that the NOV9a amino acid sequence has 63 of 184 amino acid residues (34%) identical to, and 107 of 184 amino acid residues (58%) similar to, the 377 amino acid residue ptnr:SPTREMBL-ACC:O73733 protein from *Brachydanio rerio* (Zebrafish) (*Zebra danio*) (Neuropeptide Y/Peptide YY Receptor YA) (E = 0.0).

10 NOV9a is predicted to be expressed in at least kidney. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

15 In addition, the sequence is predicted to be expressed in lower small intestine, colon, and pancreas, brain, hypothalamus because of SAGE tags identified for AI308124 and AI307658, ESTs which match to the sequence of the invention: pancreatic cancer, prostate, prostate cancer, brain, glioblastoma, astrocytoma, normal human luminal mammary epithelial cells, breast cancer, ovary, cystadenoma. The SAGE data is reproduced in Example 5. The sequence is also predicted to be expressed in the following tissues because of the expression  
20 pattern of related genes in the Neuropeptide Y/Peptide YY/ Orexin/ Galanin/ Cholecystokinin receptor family.

#### NOV9b

In the present invention, the target sequence identified previously, NOV9a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by  
25 starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on  
30 silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein

sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated NOV9b. This differs from the previously identified sequence (NOV9a) in having 38 less amino acids and 3 different ones.

A disclosed NOV9b nucleic acid of 1472 nucleotides (also referred to as CG56554-02) encoding a novel Neuropeptide Y/Peptide YY receptor -like protein is shown in Table 9C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 42-44 and ending with a TAA codon at nucleotides 1335-1337. A putative untranslated region upstream from the initiation codon and downstream from the termination codon is underlined in Table 9C. The start and stop codons are in bold letters.

In a search of public sequence databases, the NOV9b nucleic acid sequence, localized to chromosome 4, has 403 of 656 bases (61%) identical to a gb:GENBANK-ID:AB040103|acc:AB040103.1 mRNA from *Rattus norvegicus* (*Rattus norvegicus* OT7T022 mRNA for RFamide-related peptide receptor, complete cds) ( $E = 7.8e^{-13}$ ).

The disclosed NOV9b polypeptide (SEQ ID NO:48) encoded by SEQ ID NO:47 has 393 amino acid residues and is presented in Table 9D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV9b has no signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively, NOV9b may also localize to the Golgi body with a certainty of 0.4000, the endoplasmic reticulum (membrane) with a certainty of 0.3000, or in the microbody (peroxisome) with a certainty of 0.3000. The most likely cleavage site for NOV9b is between positions 64 and 65: GNA-LV.

**Table 9D. Encoded NOV9b protein sequence (SEQ ID NO:48).**

--

A search of sequence databases reveals that the NOV9b amino acid sequence has 108 of 315 amino acid residues (34%) identical to, and 180 of 315 amino acid residues (57%) similar to, the 522 amino acid residue ptnr:SWISSNEW-ACC:Q9Y5X5 protein from *Homo sapiens* (Human) (Neuropeptide Ff Receptor 2 (Neuropeptide G Protein-Coupled Receptor) (G-Protein-Coupled Receptor HLWAR77)) ( $E = 5.2e^{-46}$ ).

NOV9b is predicted to be expressed in at least the following tissues: lower small intestine, colon, and pancreas, brain, hypothalamus, kidney, pancreatic cancer, prostate, prostate cancer, glioblastoma, astrocytoma, normal human luminal mammary epithelial cells, breast cancer, ovary, cystadenoma.

The disclosed NOV9a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 9E.

**Table 9E. BLAST results for NOV9a**

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 9F. In the ClustalW alignment of the NOV9 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

The NOV9 nucleic acids and polypeptides share structure similarity to members to the Neuropeptide Y/Peptide YY/ Orexin/ Galanin/ Cholecystokinin/pancreatic polypeptide receptor family Neuropeptide Y (NPY) is one of the most abundant neuropeptides in the mammalian nervous system and exhibits a diverse range of important physiologic activities, including effects on psychomotor activity, food intake, regulation of central endocrine secretion, and potent vasoactive effects on the cardiovascular system. It shows sequence homology to peptide YY and over 50% homology in amino acid and nucleotide sequence to pancreatic polypeptide. Neuropeptide Y (NPY) signals through a family of G protein-coupled receptors present in the brain and sympathetic neurons. At least 3 types of neuropeptide Y receptor have been defined on the basis of pharmacologic criteria, tissue distribution, and structure of the encoding gene. The NPY Y1 receptors have been identified in a variety of tissues, including brain, spleen, small intestine, kidney, testis, placenta, and aortic smooth muscle. The Y2 receptor is found mainly in the central nervous system.

Orexin A and Orexin B, are derived from the same precursor, orexin, or hypocretin (HCRT), by proteolytic processing. One receptor, designated OX2R, binds both orexin A and orexin B. The predicted amino acid sequences of human and rat OX2R are 95% identical and contain 7 putative transmembrane domains. The other receptor, designated OX1R (HCRT1), binds orexin A only and has 64% identity to OX2R. Northern blot analysis revealed that in the

rat a 3.5-kb OX2R mRNA is expressed exclusively in the brain. When administered intracerebroventricularly to rats, orexin A and orexin B stimulated food consumption. In addition, preproorexin mRNA levels are upregulated upon fasting, thus these peptides are mediators in the central feedback mechanism that regulates feeding behavior.

- 5           PYY is secreted from endocrine cells in the lower small intestine, colon, and pancreas. It acts through the pancreatic polypeptide receptors in the gastrointestinal tract as an inhibitor of gastric acid secretion, gastric emptying, digestive enzyme secretion by the pancreas, and gut motility.

          The disclosed NOV9 nucleic acid of the invention encoding a Neuropeptide Y/Peptide YY receptor -like protein includes the nucleic acid whose sequence is provided in Table 9A or  
10           a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 9A while still encoding a protein that maintains its Neuropeptide Y/Peptide YY receptor -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes  
15           nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones  
20           are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 15 percent of the bases may be so changed.

25           The disclosed NOV9 protein of the invention includes the Neuropeptide Y/Peptide YY receptor -like protein whose sequence is provided in Table 9B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 9B while still encoding a protein that maintains its Neuropeptide Y/Peptide YY receptor -like activities and physiological functions, or a functional fragment  
30           thereof. In the mutant or variant protein, up to about 70 percent of the residues may be so changed.

          The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Neuropeptide Y/Peptide YY receptor-like protein (NOV9) is a member of a "Neuropeptide Y/Peptide YY receptor family". Therefore, the NOV9 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV9 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in obesity, diabetes, kidney disorders, cardiovascular disorders, anorexia, eating disorders, gastrointestinal and digestive diseases, metabolic diseases, CNS disorders, cancer, autoimmune disease, inflammation, and/or other pathologies and disorders.

NOV9 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV9 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV9 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV10

A disclosed NOV10 nucleic acid of 985 nucleotides (also referred to as CG55964-01) encoding a novel G-Protein Coupled Receptor-like protein is shown in Table 10A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 33-35 and ending with a TGA codon at nucleotides 981-983. A putative untranslated region upstream from the initiation codon is underlined in Table 10A. The start and stop codons are in bold letters.

In a search of public sequence databases, the NOV10 nucleic acid sequence has 789 of  
 974 bases (81%) identical to a gb:GENBANK-ID:AF133300|acc:AF133300.2 mRNA from  
*Mus musculus* (MOR 3'Beta1, MOR 3'Beta2, MOR 3'Beta3, and MOR 3'Beta4 genes,  
 5 complete cds; Cbx3 pseudogene, complete sequence; and MOR 3'Beta5 and MOR 3'Beta6  
 genes, complete cds) ( $E = 4.3e^{-136}$ ).

The disclosed NOV10 polypeptide (SEQ ID NO:50) encoded by SEQ ID NO:49 has  
 316 amino acid residues and is presented in Table 10B using the one-letter amino acid code.  
 Signal P, Psort and/or Hydropathy results predict that NOV10b has a signal peptide and is  
 10 likely to be localized to the endoplasmic reticulum (membrane) with a certainty of 0.6850.  
 Alternatively, NOV10 may also localize to the plasma membrane with a certainty of 0.6400,  
 the Golgi body with a certainty of 0.4600, or in the endoplasmic reticulum (lumen) with a  
 certainty of 0.1000. The most likely cleavage site for NOV10 is between positions 24 and 25:  
 LES-VQ.

15

A search of sequence databases reveals that the NOV10 amino acid sequence has 316  
 of 316 amino acid residues (100%) identical to, and 316 of 316 amino acid residues (100%)  
 similar to, the 316 amino acid residue ptrn:TREMBLNEW-ACC:AAG42368 protein from  
 20 *Homo sapiens* (Human) (Odorant Receptor HOR3'BETA5) ( $E = 5.7e^{-169}$ ).

NOV10 is predicted to be expressed in at least Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

The disclosed NOV10 polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 10C.

Table 10C. BLAST results for NOV10

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 10D. In the ClustalW alignment of the NOV10 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and

can potentially be altered to a much broader extent without altering protein structure or function.

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals.

Previously, OR genes cloned in different species were from random locations in the respective genomes. The human OR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

5           The disclosed NOV10 nucleic acid of the invention encoding a G-Protein Coupled Receptor-like protein includes the nucleic acid whose sequence is provided in Table 10A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 10A while still encoding a protein that maintains its G-Protein Coupled Receptor-like activities and physiological  
10 functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example,  
15 modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 19 percent of the bases may be so changed.

20           The disclosed NOV10 protein of the invention includes the G-Protein Coupled Receptor-like protein whose sequence is provided in Table 10B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 10B while still encoding a protein that maintains its G-Protein Coupled Receptor-like activities and physiological functions, or a functional fragment thereof.  
25 In the mutant or variant protein, up to about 25 percent of the residues may be so changed.

          The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

          The above disclosed information suggests that this G-Protein Coupled Receptor-like protein (NOV10) is a member of a "G-Protein Coupled Receptor family". Therefore, the  
30 NOV10 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene

delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV10 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in developmental diseases, MHCII and III diseases  
 5 (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial,  
 10 fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction,  
 15 ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluysian atrophy (DRPLA) Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

20 NOV10 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV10 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV10 protein has multiple hydrophilic  
 25 regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### 30 NOV11

A disclosed NOV11 nucleic acid of 1014 nucleotides (also referred to as Curagen Accession No. CG55966-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 11A. An open reading frame was identified beginning with an ATG initiation

codon at nucleotides 2-4 and ending with a TGA codon at nucleotides 947-949. Putative untranslated regions upstream from the initiation codon and downstream of the termination codon are underlined in Table 11A. The start and stop codons are in bold letters.

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals. Previously, OR genes cloned in different species were from random locations in the respective genomes. The human OR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV11 nucleic acid of the invention encoding a G-Protein Coupled Receptor-like protein includes the nucleic acid whose sequence is provided in Table 11A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 11A while still encoding a protein that maintains its G-Protein Coupled Receptor-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example,

modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject.

- 5       The disclosed NOV11 protein of the invention includes the G-Protein Coupled Receptor-like protein whose sequence is provided in Table 11B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 11B while still encoding a protein that maintains its G-Protein Coupled Receptor-like activities and physiological functions, or a functional fragment thereof.
- 10   In the mutant or variant protein, up to about 47 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

- The above disclosed information suggests that this G-Protein Coupled Receptor-like protein (NOV11) is a member of a "G-Protein Coupled Receptor family". Therefore, the
- 15   NOV11 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation),
- 20   research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

- The NOV11 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma,
- 25   Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain,
- 30   cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological

disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidolusian atrophy(DRPLA) Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other pathologies and disorders.

5 NOV11 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV11 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. These novel proteins can be used in assay systems for  
10 functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV12

A disclosed NOV12 nucleic acid of 1067 nucleotides (also referred to as Curagen Accession No. CG56003-01) encoding a novel G-Protein Coupled Receptor -like protein is  
15 shown in Table 12A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 15-17 and ending with a TGA codon at nucleotides 1023-1025. The untranslated regions are underlined and the start and stop codons are in bold letters in Table 12A.

**Table 12A. NOV12 nucleotide sequence (SEQ ID NO:53).**

A search of sequence databases reveals that the NOV12 amino acid sequence has 52 of 179 amino acid residues (29%) identical to, and 86 of 179 amino acid residues (48%) similar to, the 339 amino acid residue ptnr: SWISSPROT-ACC:Q13304 protein from *Homo sapiens* Putative G Protein-Coupled Receptor GPR17 (R12) ( $E = 1.6e^{-22}$ ).

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV12 polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 12C.

**Table 12C. BLAST results for NOV12**

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 12D. In the ClustalW alignment of the NOV12 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven

transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals. Previously, OR genes cloned in different species were from random locations in the respective genomes. The human OR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV12 nucleic acid of the invention encoding a G-Protein Coupled Receptor-like protein includes the nucleic acid whose sequence is provided in Table 12A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 12A while still encoding a protein that maintains its G-Protein Coupled Receptor-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject.

The disclosed NOV12 protein of the invention includes the G-Protein Coupled Receptor-like protein whose sequence is provided in Table 12B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 12B while still encoding a protein that maintains its G-Protein Coupled Receptor-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 77 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this G-Protein Coupled Receptor-like protein (NOV12) is a member of a "G-Protein Coupled Receptor family". Therefore, the NOV12 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug

targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV12 nucleic acids and proteins of the invention are useful in potential  
 5 therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to  
 10 starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and  
 15 Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluysian atrophy (DRPLA) Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease  
 20 or Gilles de la Tourette syndrome, and/or other pathologies and disorders.

NOV12 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV12 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-  
 25 NOVX Antibodies" section below. The disclosed NOV12 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### 30 NOV13

NOV13 includes three novel G-Protein Coupled Receptor -like proteins disclosed below. The disclosed sequences have been named NOV13a and NOV13b.

#### NOV13a

A disclosed NOV13a nucleic acid of 961 nucleotides (also referred to as CG56075-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 13A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 12-14 and ending with a TGA codon at nucleotides 936-938. The start and stop codons are shown in bold in Table 13A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 13A. NOV13a nucleotide sequence (SEQ ID NO:55).**

A search of sequence databases reveals that the NOV13a amino acid sequence has 216 of 217 amino acid residues (99%) identical to, and 217 of 217 amino acid residues (100%) similar to, the 217 amino acid residue ptrn: SPTREMBL-ACC:O95224 protein from *Homo sapiens* (Human) (Olfactory Receptor) ( $E = 2.2e^{-109}$ ).

#### NOV13b

A disclosed NOV13b nucleic acid of 961 nucleotides (also referred to as CG56021-02) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 13C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 12-14 and ending with a TGA codon at nucleotides 936-938. A putative untranslated region upstream

from the initiation codon is underlined in Table 13C. The start and stop codons are in bold letters.

**GAGGCTTGGAAATCTCACACTGACA**

In a search of public sequence databases, the NOV13b nucleic acid sequence has 648  
 5 of 653 bases (99%) identical to a gb:GENBANK-ID:AF065876|acc:AF065876.1 mRNA from  
*Homo sapiens* (olfactory receptor (OR2D2) gene, partial cds) ( $E = 2.8e^{-139}$ ).

The disclosed NOV13b polypeptide (SEQ ID NO:58) encoded by SEQ ID NO:57 has  
 308 amino acid residues and is presented in Table 13D using the one-letter amino acid code.  
 Signal P, Psort and/or Hydropathy results predict that NOV13b has a signal peptide and is  
 10 likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively,  
 NOV13b may also localize to the Golgi body with a certainty of 0.4000, the endoplasmic  
 reticulum (membrane) with a certainty of 0.3000, or in the microbody (peroxisome) with a  
 certainty of 0.3000. The most likely cleavage site for NOV13b is between positions 53 and 54:  
 VDS-QL.

15

 SLRNKDVKAALRKVATRNF

A search of sequence databases reveals that the NOV13 amino acid sequence has 52 of  
 179 amino acid residues (29%) identical to, and 86 of 179 amino acid residues (48%) similar  
 to, the 339 amino acid residue ptrn: SWISSPROT-ACC:Q13304 protein from *Homo sapiens*  
 20 Putative G Protein-Coupled Receptor GPR17 (R12) ( $E = 3.3e^{-157}$ ).

NOV13b is predicted to be expressed in at least Apical microvilli of the retinal  
 pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines,

corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

The disclosed NOV13a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 13E.

Table 13E. BLAST results for NOV13a

15

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 13F. In the ClustalW alignment of the NOV13 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals.

5 Previously, OR genes cloned in different species were from random locations in the respective genomes. The human OR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV13 nucleic acid of the invention encoding a G-Protein Coupled  
10 Receptor -like protein includes the nucleic acid whose sequence is provided in Table 13A, 14C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 13A, or 14C while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes  
15 nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones  
20 are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 1 percent of the bases may be so changed.

25 The disclosed NOV13 protein of the invention includes the G-Protein Coupled Receptor -like protein whose sequence is provided in Table 13B, or 14D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 13B, or 14D while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a  
30 functional fragment thereof. In the mutant or variant protein, up to about 15 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this G-Protein Coupled Receptor -like protein (NOV13) is a member of a "G-Protein Coupled Receptor family". Therefore, the NOV13 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV13 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluysian atrophy (DRPLA) Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

NOV13 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV13 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV13 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in

understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV14

A disclosed NOV14 nucleic acid of 986 nucleotides (also referred to as CG56023-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 14A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 23-25 and ending with a TGA codon at nucleotides 974-976. The start and stop codons are shown in bold in Table 14A, and the 5' and 3' untranslated regions, if any, are underlined.

15

A search of sequence databases reveals that the NOV14 amino acid sequence has 234 of 310 amino acid residues (75%) identical to, and 264 of 310 amino acid residues (85%) similar to, the 315 amino acid residue ptnr: SPTREMBL-ACC:Q9JKA6 protein from *Mus musculus* (Mouse) (OLFACTORY RECEPTOR P2) ( $E = 4.0e^{-124}$ ).

The disclosed NOV14 polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 14C.

20

Table 14C. BLAST results for NOV14

10           G-Protein Coupled Receptor (GPCRs) have been identified as extremely large  
 subfamily of G protein-coupled receptors in a number of species. These receptors share a  
 seven transmembrane domain structure with many neurotransmitter and hormone receptors,  
 and are likely to underlie the recognition and G-protein-mediated transduction of various  
 signals. Previously, GPCR genes cloned in different species were from random locations in the  
 15   respective genomes. The human GPCR genes are intron less and belong to four different gene  
 subfamilies, displaying great sequence variability. These genes are dominantly expressed in  
 olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G  
 protein-coupled receptors in a number of species. These receptors share a seven  
 20   transmembrane domain structure with many neurotransmitter and hormone receptors, and are  
 likely to underlie the recognition and G-protein-mediated transduction of odorant signals.  
 Previously, OR genes cloned in different species were from random locations in the respective  
 genomes. The human OR genes are intron less and belong to four different gene subfamilies,  
 displaying great sequence variability. These genes are dominantly expressed in olfactory  
 25   epithelium.

The disclosed NOV14 nucleic acid of the invention encoding a G-Protein Coupled  
 Receptor -like protein includes the nucleic acid whose sequence is provided in Table 14A or a  
 fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose  
 bases may be changed from the corresponding base shown in Table 14A while still encoding a  
 30   protein that maintains its G-Protein Coupled Receptor -like activities and physiological  
 functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids  
 whose sequences are complementary to those just described, including nucleic acid fragments  
 that are complementary to any of the nucleic acids just described. The invention additionally  
 includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures  
 35   include chemical modifications. Such modifications include, by way of nonlimiting example,  
 modified bases, and nucleic acids whose sugar phosphate backbones are modified or  
 derivatized. These modifications are carried out at least in part to enhance the chemical  
 stability of the modified nucleic acid, such that they may be used, for example, as antisense  
 binding nucleic acids in therapeutic applications in a subject.

The disclosed NOV14 protein of the invention includes the G-Protein Coupled Receptor -like protein whose sequence is provided in Table 14B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 14B while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 12 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this G-Protein Coupled Receptor -like protein (NOV14) is a member of a "G-Protein Coupled Receptor family". Therefore, the NOV14 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV14 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluisian atrophy(DRPLA) Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

NOV14 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV14 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-  
 5 NOVX Antibodies" section below. The disclosed NOV14 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### 10 NOV15

NOV15 includes three novel G-Protein Coupled Receptor -like proteins disclosed below. The disclosed sequences have been named NOV15a and NOV15b.

#### NOV15a

A disclosed NOV15a nucleic acid of 943 nucleotides (also referred to as CG56065-01)  
 15 encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 15A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 2-4 and ending with a TGA codon at nucleotides 935-937. The start and stop codons are shown in bold in Table 15A, and the 5' and 3' untranslated regions, if any, are underlined.

A search of sequence databases reveals that the NOV15a amino acid sequence has 235  
 of 311 amino acid residues (75%) identical to, and 270 of 311 amino acid residues (86%)  
 similar to, the 311 amino acid residue ptrn: SPTREMBL-ACC:O35184 protein from *Rattus*  
 5 *norvegicus* (Rat) (Olfactory Receptor) ( $E = 9.9e^{-121}$ ).

**NOV15b**

A disclosed NOV15b nucleic acid of 943 nucleotides (also referred to as CG56065-02)  
 encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 15C. An open  
 reading frame was identified beginning with an ATG initiation codon at nucleotides 2-4 and  
 10 ending with a TGA codon at nucleotides 935-937. The start and stop codons are shown in  
 bold in Table 15C, and the 5' and 3' untranslated regions, if any, are underlined.

AACAGAA

In a search of public sequence databases, the NOV15b nucleic acid sequence, localized  
 15 to chromosome 4, has 770 of 937 bases (82%) identical to a gb:GENBANK-  
 ID:AF282271|acc:AF282271.1 mRNA from *Mus musculus* (odorant receptor K11 gene,  
 complete cds) ( $E = 5.2e^{-135}$ ).

The disclosed NOV15b polypeptide (SEQ ID NO:64) encoded by SEQ ID NO:63 has  
 311 amino acid residues and is presented in Table 15D using the one-letter amino acid code.  
 20 Signal P, Psort and/or Hydropathy results predict that NOV15b has no signal peptide and is  
 likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively,  
 NOV15b may also localize to the Golgi body with a certainty of 0.4000, the endoplasmic

reticulum (membrane) with a certainty of 0.3000, or in the microbody (peroxisome) with a certainty of 0.3000. The most likely cleavage site for NOV15b is between positions 41 and 42: VLG-NL.

**Table 15D. Encoded NOV15b protein sequence (SEQ ID NO:64).**

A search of sequence databases reveals that the NOV15b amino acid sequence has 237 of 311 amino acid residues (76%) identical to, and 273 of 311 amino acid residues (87%) similar to, the 314 amino acid residue ptnr:TREMBLNEW-ACC:AAG39856 protein from *Mus musculus* (Mouse) (Odorant Receptor K11) ( $E = 2.6e^{-125}$ ).

NOV15b is predicted to be expressed in at least the following tissues: Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

The disclosed NOV15a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 15E.

**Table 15E. BLAST results for NOV15a**

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals.

5 Previously, OR genes cloned in different species were from random locations in the respective genomes. The human OR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV15 nucleic acid of the invention encoding a G-Protein Coupled  
10 Receptor -like protein includes the nucleic acid whose sequence is provided in Table 15A, 15C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 15A or 15C while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes  
15 nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones  
20 are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 18 percent of the bases may be so changed.

25 The disclosed NOV15 protein of the invention includes the G-Protein Coupled Receptor -like protein whose sequence is provided in Table 15B, or 15D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 15B, or 15D while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a  
30 functional fragment thereof. In the mutant or variant protein, up to about 23 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this G-Protein Coupled Receptor -like protein (NOV15) is a member of a "G-Protein Coupled Receptor family". Therefore, the NOV15 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV15 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluysian atrophy (DRPLA) Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

NOV15 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV15 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV15 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in

understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV16a

- A disclosed NOV16a nucleic acid of 891 nucleotides (also referred to as CG56067-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 16A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 5-7 and ending with a TAA codon at nucleotides 878-880. The start and stop codons are shown in bold in Table 16a, and the 5' and 3' untranslated regions, if any, are underlined.

10

- In a search of public sequence databases, the NOV16a nucleic acid sequence, localized to chromosome 4, has 729 of 888 bases (82%) identical to a gb:GENBANK-ID:AF282293|acc:AF282293.1 mRNA from *Mus musculus* (odorant receptor K4h11 gene, complete cds) ( $E = 9.8e^{-127}$ ).

- The disclosed NOV16a polypeptide (SEQ ID NO:66) encoded by SEQ ID NO:65 has 311 amino acid residues and is presented in Table 16B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV16a has no signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively, NOV16A may also localize to the Golgi body with a certainty of 0.4000, the endoplasmic reticulum (membrane) with a certainty of 0.3000, or in the microbody (peroxisome) with a certainty of 0.3000. The most likely cleavage site for NOV16A is between positions 41 and 42: VVG-NL.

**Table 16B. Encoded NOV16a protein sequence (SEQ ID NO:66).**

--

A search of sequence databases reveals that the NOV16a amino acid sequence has 232 of 287 amino acid residues (80%) identical to, and 253 of 287 amino acid residues (88%) similar to, the 307 amino acid residue ptnr:TREMBLNEW-ACC:AAG39878 protein from

5 *Mus musculus* (Mouse) (Odorant Receptor K4H11) ( $E = 5.1e^{-122}$ ).

NOV16a is predicted to be expressed in at least Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and

10 umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic)

15 spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

#### NOV16b

20 A disclosed NOV16b nucleic acid of 939 nucleotides (also referred to as CG56753-02) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 16C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 1-3 and ending with a TAG codon at nucleotides 934-936. The start and stop codons are shown in bold in Table 16C, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV16b nucleic acid sequence has 770 of 935 bases (82%) identical to a gb:GENBANK-ID:AF282271|acc:AF282271.1 mRNA from *Mus musculus* (odorant receptor K11 gene, complete cds) ( $E = 1.3e^{-136}$ ).

- 5 The disclosed NOV16b polypeptide (SEQ ID NO:68) encoded by SEQ ID NO:67 has 311 amino acid residues and is presented in Table 16D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV16b has A signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively, NOV16b may also localize to the Golgi body with a certainty of 0.4000, the endoplasmic
- 10 reticulum (membrane) with a certainty of 0.3000, or in the endoplasmic reticulum (lumen) with a certainty of 0.3000. The most likely cleavage site for NOV16b is between positions 41 and 42: VVG-NL.

 IYSLRNKDVHVSLLKMLQRRLL

- 15 A search of sequence databases reveals that the NOV16b amino acid sequence has 238 of 311 amino acid residues (76%) identical to, and 274 of 311 amino acid residues (88%) similar to, the 314 amino acid residue ptnr:SPTREMBL-ACC:Q9EQB8 protein from *Mus musculus* (Mouse) (Odorant Receptor K11) ( $E = 1.0e^{-127}$ ).

- NOV16b is predicted to be expressed in at least the following tissues: Apical microvilli
- 20 of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary

artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

The disclosed NOV16a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 16E.

Table 16E. BLAST results for NOV16a

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 16F. In the ClustalW alignment of the NOV16 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals. Previously, OR genes cloned in different species were from random locations in the respective genomes. The human OR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV16 nucleic acid of the invention encoding a G-Protein Coupled Receptor -like protein includes the nucleic acid whose sequence is provided in Table 16A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 16A while still encoding a

protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally  
5 includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense  
10 binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 18 percent of the bases may be so changed.

The disclosed NOV16 protein of the invention includes the G-Protein Coupled Receptor -like protein whose sequence is provided in Table 16B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding  
15 residue shown in Table 16B while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 23 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

20 The above disclosed information suggests that this G-Protein Coupled Receptor -like protein (NOV16) is a member of a "G-Protein Coupled Receptor family". Therefore, the NOV16 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to:  
25 protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV16 nucleic acids and proteins of the invention are useful in potential  
30 therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to

starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and  
5 Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluysian atrophy(DRPLA) Hypophosphatemic rickets,  
10 autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

NOV16 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV16 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods  
15 known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV16 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various  
20 disorders.

#### **NOV17**

NOV17 includes three novel G-Protein Coupled Receptor -like proteins disclosed below. The disclosed sequences have been named NOV17a, NOV17b, NOV17c, and NOV17d.

#### **NOV17a**

A disclosed NOV17a nucleic acid of 962 nucleotides (also referred to as CG56657-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 17A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 18-20 and ending with a TAG codon at nucleotides 954-956. The start and stop codons are shown in  
30 bold in Table 17A, and the 5' and 3' untranslated regions, if any, are underlined.

A search of sequence databases reveals that the NOV17a amino acid sequence has 148 of 305 amino acid residues (48%) identical to, and 192 of 305 amino acid residues (62%) similar to, the 316 amino acid residue ptr: TREMBLNEW-ACC:AAG45196 protein from *Mus musculus* (Mouse) (T2 OLFACTORY RECEPTOR) ( $E = 8.0e^{-73}$ ).

**NOV17b**

A disclosed NOV17b nucleic acid of 962 nucleotides (also referred to as CG56657-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 17C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 18-20 and ending with a TAG codon at nucleotides 954-956. The start and stop codons are shown in bold in Table 17C, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV17b nucleic acid sequence, localized to chromosome 4, has 321 of 342 bases (93%) identical to a gb:GENBANK-  
 ID:HSHTPRH07/acc:X64978.1 mRNA from *Homo sapiens* (*H.sapiens* mRNA HTPCRH07  
 5 for olfactory receptor) ( $E = 2.9e^{-62}$ ).

The disclosed NOV17b polypeptide (SEQ ID NO:72) encoded by SEQ ID NO:71 has 311 amino acid residues and is presented in Table 17D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV17b has no signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.4600. Alternatively,  
 10 NOV17b may also localize to the microbody (peroxisome) with a certainty of 0.2311, the endoplasmic reticulum (membrane) with a certainty of 0.1000, or in the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV17B is between positions 43 and 44: NLS-MI.

15

A search of sequence databases reveals that the NOV17b amino acid sequence has 148 of 305 amino acid residues (48%) identical to, and 191 of 305 amino acid residues (62%) similar to, the 316 amino acid residue ptrn:TREMBLNEW-ACC:AAG45196 protein from *Mus musculus* (Mouse) (T2 Olfactory Receptor) ( $E = 8.0e^{-73}$ ).

20 NOV17b is predicted to be expressed in at least the following tissues: Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral

tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express  
 5 MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling  
 10 sources, Public EST sources, Literature sources, and/or RACE sources.

### NOV17c

A disclosed NOV17c nucleic acid of 883 nucleotides (also referred to as CG56659-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 17E. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 44-46 and  
 15 ending with a TAG codon at nucleotides 875-877. The start and stop codons are shown in bold in Table 17E, and the 5' and 3' untranslated regions, if any, are underlined.

A search of sequence databases reveals that the NOV17c amino acid sequence has 139 of 272 amino acid residues (51%) identical to, and 181 of 272 amino acid residues (66%) similar to, the 316 amino acid residue ptnr: TREMBLNEW-ACC:AAG45196 protein from *Mus musculus* (Mouse) (T2 OLFACTORY RECEPTOR) ( $E = 4.0e^{-71}$ ).

#### 5 NOV17d

A disclosed NOV17d nucleic acid of 926 nucleotides (also referred to as CG56659\_02) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 17G. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 87-89 and ending with a TAG codon at nucleotides 918-920. The start and stop codons are shown in  
10 bold in Table 17G, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV17d nucleic acid sequence has 343 of 343 bases (100%) identical to a gb:GENBANK-ID:HSHTPRH07|acc:X64978.1 mRNA from  
15 *Homo sapiens* (*H.sapiens* mRNA HTPCRH07 for olfactory receptor) ( $E = 5.4e^{-71}$ ).

The disclosed NOV17D polypeptide (SEQ ID NO:76) encoded by SEQ ID NO:75 has 277 amino acid residues and is presented in Table 17H using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV17d has no signal peptide and is likely to be localized to the endoplasmic reticulum (membrane) with a certainty of 0.6850.  
20 Alternatively, NOV17d may also localize to the plasma membrane with a certainty of 0.6400, the Golgi body with a certainty of 0.4600, or in the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV17D is between positions 22 and 23: HTP-MY.

**Table 17H. Encoded NOV17d protein sequence (SEQ ID NO:76).**

A search of sequence databases reveals that the NOV17d amino acid sequence has 138 of 269 amino acid residues (51%) identical to, and 183 of 269 amino acid residues (68%) similar to, the 316 amino acid residue ptnr:SPTREMBL-ACC:Q9D3U9 protein from *Mus musculus* (Mouse) (4933433E02rik Protein) ( $E = 3.9e^{-71}$ ).

NOV17d is predicted to be expressed in at least the following tissues: Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

The disclosed NOV17a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 17I.

Table 17I. BLAST results for NOV17a

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 17J. In the ClustalW alignment of the NOV17 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Table 17F lists the domain description from DOMAIN analysis results against NOV17.

This indicates that the NOV17 sequence has properties similar to those of other proteins known to contain this domain.

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the

respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G  
5 protein-coupled receptors in a number of species. These receptors share a seven  
transmembrane domain structure with many neurotransmitter and hormone receptors, and are  
likely to underlie the recognition and G-protein-mediated transduction of odorant signals.  
Previously, OR genes cloned in different species were from random locations in the respective  
genomes. The human OR genes are intron less and belong to four different gene subfamilies,  
10 displaying great sequence variability. These genes are dominantly expressed in olfactory  
epithelium.

The disclosed NOV17 nucleic acid of the invention encoding a G-Protein Coupled  
Receptor -like protein includes the nucleic acid whose sequence is provided in Table 17A,  
17C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of  
15 whose bases may be changed from the corresponding base shown in Table 17A or 17C while  
still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and  
physiological functions, or a fragment of such a nucleic acid. The invention further includes  
nucleic acids whose sequences are complementary to those just described, including nucleic  
acid fragments that are complementary to any of the nucleic acids just described. The  
20 invention additionally includes nucleic acids or nucleic acid fragments, or complements  
thereto, whose structures include chemical modifications. Such modifications include, by way  
of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones  
are modified or derivatized. These modifications are carried out at least in part to enhance the  
chemical stability of the modified nucleic acid, such that they may be used, for example, as  
25 antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or  
variant nucleic acids, and their complements, up to about 7 percent of the bases may be so  
changed.

The disclosed NOV17 protein of the invention includes the G-Protein Coupled  
Receptor -like protein whose sequence is provided in Table 17B or 17D. The invention also  
30 includes a mutant or variant protein any of whose residues may be changed from the  
corresponding residue shown in Table 17B or 17D while still encoding a protein that  
maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a  
functional fragment thereof. In the mutant or variant protein, up to about 54 percent of the  
residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this G-Protein Coupled Receptor -like protein (NOV17) is a member of a "G-Protein Coupled Receptor family". Therefore, the NOV17 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV17 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidolusian atrophy (DRPLA) Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

NOV17 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV17 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV17 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in

assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV18

5 NOV18 includes three novel G-Protein Coupled Receptor -like proteins disclosed below. The disclosed sequences have been named NOV18a and NOV18b.

### NOV18a

A disclosed NOV18a nucleic acid of 1062 nucleotides (also referred to as CG56663-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 18A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 10-12 and ending with a TAA codon at nucleotides 948-950. The start and stop codons are shown in bold in Table 18A, and the 5' and 3' untranslated regions, if any, are underlined.

A search of sequence databases reveals that the NOV18a amino acid sequence has 194  
20 of 237 amino acid residues (81%) identical to, and 215 of 237 amino acid residues (90%)

similar to, the 237 amino acid residue ptnr: SPTREMBL-ACC:Q9R0G5 protein from *Marmota marmota* (European marmot) (Olfactory Receptor) ( $E = 3.5e^{-102}$ ).

### NOV18b

A disclosed NOV18b nucleic acid of 1062 nucleotides (also referred to as CG56663-02) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 18C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 6-8 and ending with a TAA codon at nucleotides 948-950. The start and stop codons are shown in bold in Table 18C, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV18b nucleic acid sequence has 600 of 710 bases (84%) identical to a gb:GENBANK-ID:AX008326|acc:AX008326.1 mRNA from *Marmota marmota* (Sequence 24 from Patent WO9967282) ( $E = 8.8e^{-109}$ ).

The disclosed NOV18D polypeptide (SEQ ID NO:80) encoded by SEQ ID NO:79 has 314 amino acid residues and is presented in Table 18D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV18b has A signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively, NOV18b may also localize to the Golgi body with a certainty of 0.4000, the endoplasmic reticulum (membrane) with a certainty of 0.3000, or in the endoplasmic reticulum (lumen) with a certainty of 0.3000. The most likely cleavage site for NOV18b is between positions 42 and 43: LVG-NT.

A search of sequence databases reveals that the NOV18b amino acid sequence has 183 of 305 amino acid residues (60%) identical to, and 237 of 305 amino acid residues (77%) similar to, the 320 amino acid residue ptmr:SPTREMBL-ACC:Q9Y3N9 protein from *Homo sapiens* (Human) (DJ88J8.1 (Novel 7 Transmembrane Receptor (Rhodopsin Family) (Olfactory Receptor Like) Protein) (HS6M1-15))) ( $E = 2.8e^{-98}$ ).

NOV18b is predicted to be expressed in at least the following tissues: Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

The disclosed NOV18a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 18E.

Table 18E. BLAST results for NOV18a

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 18F. In the ClustalW alignment of the NOV18 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Tables 18G lists the domain descriptions from DOMAIN analysis results against  
 35 NOV18. This indicates that the NOV18 sequence has properties similar to those of other  
 proteins known to contain this domain.

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a  
5 seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in  
10 olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals.  
15 Previously, OR genes cloned in different species were from random locations in the respective genomes. The human OR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV18 nucleic acid of the invention encoding a G-Protein Coupled  
20 Receptor -like protein includes the nucleic acid whose sequence is provided in Table 18A, 20C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 18A or 20C while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes  
25 nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones  
30 are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 16 percent of the bases may be so changed.

The disclosed NOV18 protein of the invention includes the G-Protein Coupled Receptor -like protein whose sequence is provided in Table 18B or 20D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 18B or 20D while still encoding a protein that  
5 maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 40 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

10 The above disclosed information suggests that this G-Protein Coupled Receptor -like protein (NOV18) is a member of a "G-Protein Coupled Receptor family". Therefore, the NOV18 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to:  
15 protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV18 nucleic acids and proteins of the invention are useful in potential  
20 therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to  
25 starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and  
30 Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluysian atrophy(DRPLA) Hypophosphatemic rickets,

autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

NOV18 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV18 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV18 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV19

NOV19 includes three novel G-Protein Coupled Receptor -like proteins disclosed below. The disclosed sequences have been named NOV19a and NOV19b.

#### NOV19a

A disclosed NOV19a nucleic acid of 1046 nucleotides (also referred to as CG56665-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 19A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 14-16 and ending with a TGA codon at nucleotides 1019-1021. The start and stop codons are shown in bold in Table 19A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 19A. NOV19a nucleotide sequence (SEQ ID NO:81).**

A search of sequence databases reveals that the NOV19a amino acid sequence has 155 of 309 amino acid residues (50%) identical to, and 199 of 309 amino acid residues (64%) similar to, the 316 amino acid residue ptrn: TREMBLNEW-ACC:AAG45196 protein from  
 5 *Mus musculus* (Mouse) (T2 Olfactory Receptor) ( $E = 9.3e^{-79}$ ).

**NOV19b**

A disclosed NOV19b nucleic acid of 1046 nucleotides (also referred to as CG56665-02) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 19C. An  
 10 open reading frame was identified beginning with an ATG initiation codon at nucleotides 59-60 and ending with a TGA codon at nucleotides 1019-1021. The start and stop codons are shown in bold in Table 19C, and the 5' and 3' untranslated regions, if any, are underlined.

15 In a search of public sequence databases, the NOV19b nucleic acid sequence has 592 of 910 bases (65%) identical to a gb:GENBANK-ID:GGCOR4GEN|acc:X94744.1 mRNA from *Gallus gallus* (*G.gallus* cor4 DNA for olfactory receptor 4) ( $E = 7.8e^{-48}$ ).

The disclosed NOV19b polypeptide (SEQ ID NO:84) encoded by SEQ ID NO:83 has 320 amino acid residues and is presented in Table 19D using the one-letter amino acid code.  
 20 Signal P, Psort and/or Hydropathy results predict that NOV19b has A signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.4600. Alternatively,

NOV19b may also localize to the microbody (peroxisome) with a certainty of 0.2188, the endoplasmic reticulum (membrane) with a certainty of 0.1000, or in the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV19b is between positions 40 and 41: ALT-GN.

5

A search of sequence databases reveals that the NOV19b amino acid sequence has 155 of 306 amino acid residues (50%) identical to, and 198 of 306 amino acid residues (64%) similar to, the 316 amino acid residue ptrn:TREMBLNEW-ACC:BAB30304 protein from *Mus musculus* (Mouse) (Adult Male Testis cDNA, Riken Full-Length Enriched Library, Clone:4932441h21, Full Insert Sequence) ( $E = 1.3e^{-79}$ ).

NOV19b is predicted to be expressed in at least the following tissues: Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

The disclosed NOV19a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 19E.

| Table 19E. BLAST results for NOV19a         |                                                                                                                             |                |                  |                  |        |

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 19F. In the ClustalW alignment of the NOV19 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

10

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals. Previously, OR genes cloned in different species were from random locations in the respective genomes. The human OR genes are intron less and belong to four different gene subfamilies,

displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV19 nucleic acid of the invention encoding a G-Protein Coupled Receptor -like protein includes the nucleic acid whose sequence is provided in Table 19A, 19C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 19A or 19C while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 35 percent of the bases may be so changed.

The disclosed NOV19 protein of the invention includes the G-Protein Coupled Receptor -like protein whose sequence is provided in Table 19B or 19D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 19B or 19D while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 52 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this G-Protein Coupled Receptor -like protein (NOV19) is a member of a "G-Protein Coupled Receptor family". Therefore, the NOV19 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene

delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV19 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding disorders; control of feeding; potential obesity due to over-eating; potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluysian atrophy (DRPLA) Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

NOV19 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV19 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV19 protein has multiple hydrophilic regions; each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV20

A disclosed NOV20 nucleic acid of 1027 nucleotides (also referred to as CG56665-01) encoding a novel G-Protein Coupled Receptor -like protein is shown in Table 20A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 1-3 and ending with a TAG codon at nucleotides 940-942. The start and stop codons are shown in bold in Table 20A, and the 5' and 3' untranslated regions, if any, are underlined.

A search of sequence databases reveals that the NOV20 amino acid sequence has 134 of 278 amino acid residues (48%) identical to, and 179 of 278 amino acid residues (64%) similar to, the 321 amino acid residue ptrn: SPTREMBL-ACC:Q9UGF5 BA150A6.4 protein from *Homo sapiens* (Human) (NOVEL 7 TRANSMEMBRANE RECEPTOR (RHODOPSIN FAMILY)) ( $E = 2.4e^{-64}$ ).

10

The disclosed NOV20 polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 20C.

**Table 20C. BLAST results for NOV20**

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 20D. In the ClustalW alignment of the NOV20 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

G-Protein Coupled Receptor (GPCRs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of various signals. Previously, GPCR genes cloned in different species were from random locations in the respective genomes. The human GPCR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large subfamily of G protein-coupled receptors in a number of species. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals. Previously, OR genes cloned in different species were from random locations in the respective genomes. The human OR genes are intron less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV20 nucleic acid of the invention encoding a G-Protein Coupled Receptor -like protein includes the nucleic acid whose sequence is provided in Table 20A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 20A while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical

stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject.

The disclosed NOV20 protein of the invention includes the G-Protein Coupled Receptor -like protein whose sequence is provided in Table 20B. The invention also includes  
5 a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 20B while still encoding a protein that maintains its G-Protein Coupled Receptor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 54 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or  
10 (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this G-Protein Coupled Receptor -like protein (NOV20) is a member of a "G-Protein Coupled Receptor family". Therefore, the NOV20 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated  
15 below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV20 nucleic acids and proteins of the invention are useful in potential  
20 therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding  
25 disorders; control of feeding; potential obesity due to over-eating; potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension,  
30 hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluysian atrophy (DRPLA) Hypophosphatemic rickets,

autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

NOV20 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV20 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV20 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV21

NOV21 includes three novel adrenal secretory serine protease-like proteins disclosed below. The disclosed sequences have been named NOV21a and NOV21b.

### NOV21a

A disclosed NOV21a nucleic acid of 1028 nucleotides (also referred to as CG56639-01) encoding a novel adrenal secretory serine protease-like protein is shown in Table 21A. An open reading frame was identified beginning with an TCG initiation codon at nucleotides 1-3 and ending with a TGA codon at nucleotides 769-771. The start and stop codons are shown in bold in Table 21A, and the 5' and 3' untranslated regions, if any, are underlined. Because the start codon of NOV21a is not a traditional initiation codon, NOV21a could be a partial reading frame that extends further in the 5' direction.

**Table 21A. NOV21a nucleotide sequence (SEQ ID NO:87).**

In a search of public sequence databases, the NOV21a nucleic acid sequence, located on chromosome 19, has 296 of 466 bases (63%) identical to a gb:GENBANK-ID:E13204|acc:E13204.1 mRNA from *Homo sapiens* (Human cDNA encoding a serine protease) ( $E = 3.9e^{-18}$ ).

5 The disclosed NOV21a polypeptide (SEQ ID NO:88) encoded by SEQ ID NO:87 has 256 amino acid residues and is presented in Table 21B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV21a has A signal peptide and is likely to be localized to the microbody (peroxisome) with a certainty of 0.7480. Alternatively, NOV21a may also localize to the lysosome (lumen) with a certainty of 0.3168, or the  
10 mitochondrial matrix space with a certainty of 0.1000. The most likely cleavage site for NOV21a is between positions 68 and 69: SAA-HC.

**Table 21B. Encoded NOV21a protein sequence (SEQ ID NO:88).**

|                                                                                                                                                                                                                                                                           |

|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

A search of sequence databases reveals that the NOV21a amino acid sequence has 99  
15 of 250 amino acid residues (39%) identical to, and 134 of 250 amino acid residues (53%) similar to, the 279 amino acid residue ptnr:SPTREMBL-ACC:Q9QZ74 protein from *Rattus norvegicus* (Rat) (Adrenal Secretory Serine Protease Precursor) ( $E = 1.5e^{-42}$ ).

NOV21a is predicted to be expressed in at least the following tissues: Ovary, kidney, breast, lung, muscle, liver, spleen, blood, lymphocyte. This information was derived by  
20 determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

#### **NOV21b**

In the present invention, the target sequence identified previously, NOV21a, was  
25 subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of  
30 the reverse primer, until the stop codon was reached. Such primers were designed based on in silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein

sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated Accession Number NOV21b. This differs from the previously identified sequence (NOV21a) in being a splice variant and a mature protein starting with serine.

A disclosed NOV21b nucleic acid of 785 nucleotides (also referred to as CG56639-02) encoding a novel adrenal secretory serine protease-like protein is shown in Table 21C. An open reading frame was identified beginning with an CTT initiation codon at nucleotides 1-3 and ending with a TGA codon at nucleotides 783-785. The start and stop codons are shown in bold in Table 21C, and the 5' and 3' untranslated regions, if any, are underlined. Because the start codon of NOV21b is not a traditional initiation codon, NOV21b could be a partial reading frame that extends further in the 5' direction.

In a search of public sequence databases, the NOV21b nucleic acid sequence, located on chromosome 19, has 160 of 162 bases (98%) identical to a gb:GENBANK-

ID:HUMLAMBBB|acc:M94363.1 mRNA from *Homo sapiens* (Human lamin B2 (LAMB2) gene and ppv1 gene sequence) ( $E = 4.3e^{-59}$ ).

The disclosed NOV21b polypeptide (SEQ ID NO:90) encoded by SEQ ID NO:89 has 260 amino acid residues and is presented in Table 21D using the one-letter amino acid code.

- 5 Signal P, Psort and/or Hydropathy results predict that NOV21b has A signal peptide and is likely to be localized to the microbody (peroxisome) with a certainty of 0.7480. Alternatively, NOV21b may also localize to the lysosome (lumen) with a certainty of 0.3082, or the mitochondrial matrix space with a certainty of 0.1000. The most likely cleavage site for NOV21b is between positions 68 and 69: SAA-HC.

10

**Table 21D. Encoded NOV21b protein sequence (SEQ ID NO:90).**

|                                                                                                                                                                                                                                                                                 |

A search of sequence databases reveals that the NOV21b amino acid sequence has 123 of 250 amino acid residues (49%) identical to, and 154 of 250 amino acid residues (61%) similar to, the 855 amino acid residue ptnr:SPTREMBL-ACC:Q9Y5Y6 protein from *Homo sapiens* (Human) (Matriptase) ( $E = 3.5e^{-59}$ ).

15

NOV21b is predicted to be expressed in at least the following tissues: adrenal gland, Ovary, kidney, breast, lung, muscle, liver, spleen, blood, lymphocyte. .

The disclosed NOV21a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 21E..

20

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 21F. In the ClustalW alignment of the NOV21 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Proteolytic enzymes that exploit serine in their catalytic activity are ubiquitous, being found in viruses, bacteria and eukaryotes . They include a wide range of peptidase activity, including exopeptidase, endopeptidase, oligopeptidase and omega-peptidase activity. Over 20 families (denoted S1 - S27) of serine protease have been identified, these being grouped into 6  
5 clans on the basis of structural similarity and other functional evidence.

Tryptase is a tetrameric serine protease that is concentrated and stored selectively in the secretory granules of all types of mast cells, from which it is secreted during mast cell degranulation. Its exclusive presence in mast cells permits its use as a specific clinical indicator of mast cell activation by measurement of its level in biologic fluids and as a  
10 selective marker of intact mast cells using immunohistochemical techniques with antitryptase antibodies.

In addition, NOV21 nucleic acids and polypeptides are useful, inter alia, as novel members of the protein families according to the presence of domains and sequences related to previously described proteins. For example, NOV21 nucleic acids and polypeptides contain a  
15 structural motif that is characteristic of protein sbelonging to the serine protease family of proteins. Accordingly, NOV21 may be useful in the same ways other members of this family are useful as detailed above.

The disclosed NOV21 nucleic acid of the invention encoding a Adrenal secretory serine protease -like protein includes the nucleic acid whose sequence is provided in Table  
20 21A, 21C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 21A or 21C while still encoding a protein that maintains its Adrenal secretory serine protease -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described,  
25 including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least  
30 in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 2 percent of the bases may be so changed.

The disclosed NOV21 protein of the invention includes the Adrenal secretory serine protease -like protein whose sequence is provided in Table 21B or 24D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 21B or 21D while still encoding a protein that maintains its Adrenal secretory serine protease -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 54 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Adrenal secretory serine protease -like protein (NOV21) is a member of a "Adrenal secretory serine protease family". Therefore, the NOV21 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV21 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Von Hippel-Lindau (VHL) syndrome, cirrhosis, transplantation, endometriosis, fertility, anemia, ataxia-telangiectasia, autoimmune disease, hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, allergies, immunodeficiencies, graft versus host disease (GVHD), lymphoedema, muscular dystrophy, Lesch-Nyhan syndrome, myasthenia gravis, and/or other diseases and pathologies.

NOV21 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV21 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV21 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

## NOV22

NOV22 includes three novel adrenal secretory serine protease-like proteins disclosed below. The disclosed sequences have been named NOV22a, and NOV22b.

#### NOV22a

A disclosed NOV22a nucleic acid of 796 nucleotides (also referred to as CG56643-01) encoding a novel adrenal secretory serine protease-like protein is shown in Table 22A. An open reading frame was identified beginning with an ACC initiation codon at nucleotides 1-3 and ending with a TGA codon at nucleotides 763-765. The start and stop codons are shown in bold in Table 22A, and the 5' and 3' untranslated regions, if any, are underlined. Because the start codon of NOV22a is not a traditional initiation codon, NOV22a could be a partial reading frame that extends further in the 5' direction.

**Table 22A. NOV22a nucleotide sequence (SEQ ID NO:91).**

In a search of public sequence databases, the NOV22a nucleic acid sequence, located on chromosome 19, has 278 of 428 bases (64%) identical to a gb:GENBANK-

15 ID:E13204|acc:E13204.1 mRNA from *Homo sapiens* (Human cDNA encoding a serine protease) ( $E = 1.6e^{-29}$ ).

The disclosed NOV22a polypeptide (SEQ ID NO:92) encoded by SEQ ID NO:91 has 254 amino acid residues and is presented in Table 22B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV22a has no signal peptide and is  
20 likely to be localized to the microbody (peroxisome) with a certainty of 0.5090. Alternatively, NOV22a may also localize to the cytoplasm with a certainty of 0.4500, to the lysosome (lumen) with a certainty of 0.2082, or the mitochondrial matrix space with a certainty of 0.1000.

**Table 22B. Encoded NOV22a protein sequence (SEQ ID NO:92).**

A search of sequence databases reveals that the NOV22a amino acid sequence has 100 of 241 amino acid residues (41%) identical to, and 149 of 241 amino acid residues (61%) similar to, the 273 amino acid residue ptnr:TREMBLNEW-ACC:BAB20278 protein from *Mus musculus* (Mouse) (Type 1 Spinesin) ( $E = 3.1e^{-49}$ ).

The adrenal secretory serine protease disclosed in this invention is predicted to be expressed in at least the following tissues: Ovary, kidney, breast, lung, muscle, liver, spleen, blood, lymphocyte. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

#### NOV22b

In the present invention, the target sequence identified previously, NOV22a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on in silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated NOV22b. This differs from the previously

identified sequence (NOV22a) in having 43 additional aminoacids and different N and C terminus.

A disclosed NOV22b nucleic acid of 992 nucleotides (also referred to as CG56643-02) encoding a novel adrenal secretory serine protease-like protein is shown in Table 22C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 101-103 and ending with a TAA codon at nucleotides 920-922. The start and stop codons are shown in bold in Table 22C, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV22b nucleic acid sequence, located on chromosome 19, has 203 of 294 bases (69%) identical to a gb:GENBANK-ID:AF133086|acc:AF133086.1 mRNA from *Homo sapiens* (membrane-type serine protease 1 mRNA, complete cds) ( $E = 3.6e^{-16}$ ).

The disclosed NOV22b polypeptide (SEQ ID NO:94) encoded by SEQ ID NO:93 has 273 amino acid residues and is presented in Table 22D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV22b has A signal peptide and is likely to be localized to the mitochondrial inner membrane with a certainty of 0.8723. Alternatively, NOV22b may also localize to the plasma membrane with a certainty of 0.6500, to the mitochondrial intermembrane space with a certainty of 0.5053, or the mitochondrial matrix space with a certainty of 0.3617. The most likely cleavage site for NOV22b is between positions 43 and 44: GDA-AS.

**Table 22D. Encoded NOV22b protein sequence (SEQ ID NO:94).**

A search of sequence databases reveals that the NOV22b amino acid sequence has 49 of 90 amino acid residues (54%) identical to, and 63 of 90 amino acid residues (70%) similar to, the 277 amino acid residue ptnr:SPTREMBL-ACC:O96899 protein from *Scolopendra subspinipes* (Plasminogen Activator Spa) ( $E = 4.3e^{-24}$ ).

NOV22b is predicted to be expressed in at least the following tissues: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain - whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea and uterus. .

### NOV22c

A disclosed NOV22c nucleic acid of 912 nucleotides (also referred to as CG56643-03) encoding a novel adrenal secretory serine protease-like protein is shown in Table 22E. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 77-79 and ending with a TAA codon at nucleotides 896-898. The start and stop codons are shown in bold in Table 22E, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV22c nucleic acid sequence, located on chromosome 19, has 203 of 294 bases (69%) identical to a gb:GENBANK-ID:E13204|acc:E13204.1 mRNA from *Homo sapiens* (Human cDNA encoding a serine protease) ( $E = 1.3e^{-18}$ ).

The disclosed NOV22c polypeptide (SEQ ID NO:96) encoded by SEQ ID NO:95 has 273 amino acid residues and is presented in Table 22F using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV22c has A signal peptide and is

likely to be localized to the mitochondrial inner membrane with a certainty of 0.8723.

Alternatively, NOV22c may also localize to the plasma membrane with a certainty of 0.6500, to the mitochondrial intermembrane space with a certainty of 0.5053, or the mitochondrial matrix space with a certainty of 0.3617. The most likely cleavage site for NOV22c is between positions 43 and 44: GDA-AS.

Tables 22I-J lists the domain descriptions from DOMAIN analysis results against NOV22. This indicates that the NOV22 sequence has properties similar to those of other proteins known to contain this domain.

**Table 22I Domain Analysis of NOV22**

gnl|Smart|smart00020, Tryp\_SPC, Trypsin-like serine protease; Many of these are synthesised as inactive precursor zymogens that are cleaved during limited proteolysis to generate their active forms. A few, however, are active as single chain molecules, and others are inactive due to substitutions of the catalytic triad residues. (SEQ ID NO:812)  
 CD-Length = 230 residues, 100.0% aligned

- 5 Proteolytic enzymes that exploit serine in their catalytic activity are ubiquitous, being found in viruses, bacteria and eukaryotes [1]. They include a wide range of peptidase activity, including exopeptidase, endopeptidase, oligopeptidase and omega-peptidase activity. Over 20 families (denoted S1 - S27) of serine protease have been identified, these being grouped into 6 clans on the basis of structural similarity and other functional evidence [1].
- 10 Trypsin is a tetrameric serine protease that is concentrated and stored selectively in the secretory granules of all types of mast cells, from which it is secreted during mast cell degranulation. Its exclusive presence in mast cells permits its use as a specific clinical indicator of mast cell activation by measurement of its level in biologic fluids and as a selective marker of intact mast cells using immunohistochemical techniques with antitrypsin
- 15 antibodies. Vanderslice [2] demonstrated the existence of multiple trypsins. In this respect, mast cell trypsin is like other serine proteases such as glandular kallikrein and trypsin, which are also members of multigene families. Miller et al. [3] mapped both alpha-trypsin and beta-trypsin to human chromosome 16 by PCR analysis of DNA from human/hamster somatic cell hybrids. Miller et al. [3] cloned a second cDNA for human trypsin, called beta-trypsin, from
- 20 a mast cell cDNA library. The 1,142 bases of beta-trypsin were found to encode a 30-amino acid leader sequence of 3,089 daltons and a 245-amino acid catalytic region of 27,458 daltons. The amino acid sequence of beta-trypsin was found to be 90% identical with that of alpha-trypsin, the first 20 amino acids of the catalytic portions being 100% identical. Both alpha- and beta-trypsin sequences were localized to human chromosome 16 by analysis of DNA
- 25 preparations from 25 human/hamster somatic cell hybrids by PCR.

Because of the presence of the trypsin domains and the homology to the adrenal secretory serine protease, we anticipate that the novel sequence described here will have useful properties and functions similar to these genes.

- The disclosed NOV22 nucleic acid of the invention encoding a Adrenal secretory
- 30 serine protease -like protein includes the nucleic acid whose sequence is provided in Table 22A, 25C, 25E or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 22A, 25C, or 25E while still encoding a protein that maintains its Adrenal secretory serine protease -like activities and physiological functions, or a fragment of such a nucleic acid. The
- 35 invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids

just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least  
5 in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 36 percent of the bases may be so changed.

The disclosed NOV22 protein of the invention includes the Adrenal secretory serine  
10 protease -like protein whose sequence is provided in Table 22B, 25D, or 25F. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 22B, 25D, or 25F while still encoding a protein that maintains its Adrenal secretory serine protease -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 57 percent of the  
15 residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Adrenal secretory serine protease -like protein (NOV22) is a member of a "Adrenal secretory serine protease family". Therefore,  
20 the NOV22 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene  
25 delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV22 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Von Hippel-Lindau (VHL) syndrome, cirrhosis, transplantation, endometriosis, fertility, anemia, ataxia-telangiectasia, autoimmune disease,  
30 hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, allergies, immunodeficiencies, graft versus host disease (GVHD), lymphoedema, muscular dystrophy, Lesch-Nyhan syndrome, myasthenia gravis, and/or other diseases and pathologies.

NOV22 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV22 substances for use in

therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV22 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV23

NOV23 includes three novel serine protease DESC1 protease-like proteins disclosed below. The disclosed sequences have been named NOV23a, NOV23b, NOV23c, and NOV23d.

### NOV23a

The disclosed NOV23a nucleic acid of 1546 nucleotides (also referred to as CG56647-02) encoding a novel serine protease DESC1-like protein is shown in Table 23A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 101-103 and ending with a TAG codon at nucleotides 1481-1483. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 23A, and the start and stop codons are in bold letters.

**CATAAT**

The disclosed NOV23a nucleic acid sequence, located on chromosome 19, has 356 of 566 bases (62%) identical to a gb:GENBANK-ID:AF133086|acc:AF133086.1 mRNA from *Homo sapiens* (membrane-type serine protease 1 mRNA, complete cds) ( $E = 1.1e^{-23}$ ).

A disclosed NOV23a polypeptide (SEQ ID NO:98) encoded by SEQ ID NO:97 is 460 amino acid residues and is presented using the one-letter amino acid code in Table 23B. Signal P, Psort and/or Hydropathy results predict that NOV23a contains no signal peptide and is likely to be localized in the microbody (peroxisome) with a certainty of 0.5387.

The disclosed NOV23a amino acid sequence has 112 of 248 amino acid residues (45%) identical to, and 157 of 248 amino acid residues (63%) similar to, the 422 amino acid residue ptnr:SPTREMBL-ACC:Q9UL52 protein from *Homo sapiens* (Human) (serine protease DESC1) ( $E = 1.1e^{-58}$ ).

NOV23a is predicted to be expressed in at least Ovary, kidney, breast, lung, muscle, liver, spleen, blood and lymphocyte. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, and/or RACE sources.

### NOV23b

A disclosed NOV23b nucleic acid of 1777 nucleotides (also referred to as CG56647-03) encoding a novel serine protease DESC1-like protein is shown in Table 23C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 101-103 and ending with a TAG codon at nucleotides 1631-1633. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 23C, and the start and stop codons are in bold letters.

The disclosed NOV23b nucleic acid sequence, located on chromosome 19, has 208 of 327 bases (63%) identical to a gb:GENBANK-ID:AF098327|acc:AF098327.1 mRNA from *Homo sapiens* (putative mast cell mMCP-7-like II typtase gene, complete cds) ( $E = 2.8e^{-14}$ ).

- 5 A disclosed NOV23b polypeptide (SEQ ID NO:100) encoded by SEQ ID NO:99 is 510 amino acid residues and is presented using the one-letter amino acid code in Table 23D. Signal P, Psort and/or Hydropathy results predict that NOV23b contains no signal peptide and is likely to be localized in the microbody (peroxisome) with a certainty of 0.5131.

**Table 23D. Encoded NOV23b protein sequence (SEQ ID NO:100).**

10 The disclosed NOV23b amino acid sequence has 109 of 246 amino acid residues (44%) identical to, and 152 of 246 amino acid residues (61%) similar to, the 422 amino acid residue ptnr:SPTREMBL-ACC:Q9UL52 protein from *Homo sapiens* (Human) (serine protease DESC1) ( $E = 1.3e^{-55}$ ).

- 15 NOV23b is predicted to be expressed in at least the following tissues: adrenal gland, bone marrow, brain-amygdala, brain-cerebellum, brain-hippocampus, brain-substantia nigra, brain-thalamus, brain-whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma-Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea and  
20 uterus. Expression information was derived from the tissue sources of the sequences that were included in the derivation of the NOV23b sequence.

**NOV23c**

A disclosed NOV23c nucleic acid of 815 nucleotides (also referred to as CG56647-01) encoding a novel adrenal secretory serine protease-like protein is shown in Table 23E. An open reading frame was identified beginning with a GGT initiation codon at nucleotides 1-3 and ending with a TAA codon at nucleotides 787-789. The start and stop codons are shown in bold in Table 23E, and the 5' and 3' untranslated regions, if any, are underlined. Because the start codon of NOV23c is not a traditional initiation codon, NOV23c could be a partial reading frame that extends further in the 5' direction.

**Table 23E. NOV23c nucleotide sequence (SEQ ID NO:101).**

In a search of public sequence databases, the NOV23c nucleic acid sequence, located on chromosome 19, has 350 of 564 bases (62%) identical to a gb:GENBANK-ID:E13204|acc:E13204.1 mRNA from *Homo sapiens* (Human cDNA encoding a serine protease) ( $E = 3.2e^{-26}$ ).

The disclosed NOV23c polypeptide (SEQ ID NO:102) encoded by SEQ ID NO:101 has 262 amino acid residues and is presented in Table 23F using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV23c has no signal peptide and is likely to be localized extracellularly with a certainty of 0.3750. Alternatively, NOV23c may also localize to the microbody (peroxisome) with a certainty of 0.1391, to the endoplasmic reticulum (membrane) with a certainty of 0.1000, or the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV23c is between positions 15 and 16: CLA-EC.

A search of sequence databases reveals that the NOV23c amino acid sequence has 114 of 248 amino acid residues (45%) identical to, and 152 of 248 amino acid residues (61%) similar to, the 273 amino acid residue ptnr:TREMBLNEW-ACC:BAB20278 protein from *Mus musculus* (Mouse) (Type 1 Spinesin) ( $E = 1.1e^{-53}$ ).

NOV23c is predicted to be expressed in at least the following tissues: Ovary, kidney, breast, lung, muscle, liver, spleen, blood, lymphocyte. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

The disclosed NOV23a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 23G.

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 23H. In the ClustalW alignment of the NOV23 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate

regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

10

Proteolytic enzymes that exploit serine in their catalytic activity are ubiquitous, being found in viruses, bacteria and eukaryotes. They include a wide range of peptidase activity, including exopeptidase, endopeptidase, oligopeptidase and omega-peptidase activity. Over 20 families (denoted S1 - S27) of serine protease have been identified, these being grouped into 6  
 15 clans on the basis of structural similarity and other functional evidence.

Tryptase is a tetrameric serine protease that is concentrated and stored selectively in the secretory granules of all types of mast cells, from which it is secreted during mast cell degranulation. Its exclusive presence in mast cells permits its use as a specific clinical indicator of mast cell activation by measurement of its level in biologic fluids and as a  
 20 selective marker of intact mast cells using immunohistochemical techniques with antitryptase antibodies. Vanderslice demonstrated the existence of multiple tryptases. In this respect, mast cell tryptase is like other serine proteases such as glandular kallikrein and trypsin, which are also members of multigene families. Miller et al. mapped both alpha-tryptase and beta-tryptase to human chromosome 16 by PCR analysis of DNA from human/hamster somatic cell hybrids.  
 25 Miller et al. cloned a second cDNA for human tryptase, called beta-tryptase, from a mast cell cDNA library. The 1,142 bases of beta-tryptase were found to encode a 30-amino acid leader

sequence of 3,089 daltons and a 245-amino acid catalytic region of 27,458 daltons. The amino acid sequence of beta-tryptase was found to be 90% identical with that of alpha-tryptase, the first 20 amino acids of the catalytic portions being 100% identical. Both alpha- and beta-tryptase sequences were localized to human chromosome 16 by analysis of DNA preparations  
5 from 25 human/hamster somatic cell hybrids by PCR.

Because of the presence of the trypsin domains and the homology to the adrenal secretory serine protease, it is anticipated that the novel sequences described here will have useful properties and functions similar to these proteins.

The disclosed NOV23 nucleic acid of the invention encoding an Adrenal secretory  
10 serine protease -like protein includes the nucleic acids whose sequences are provided in Tables 23A, 23C, 23E or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 23A, 23c, or 23E while still encoding a protein that maintains its Adrenal secretory serine protease -like activities and physiological functions, or a fragment of such a nucleic acid. The invention  
15 further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar  
20 phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 37 percent of the bases may be so changed.

25 The disclosed NOV23 protein of the invention includes the Adrenal secretory serine protease -like protein whose sequence are provided in Table 23B, 23D, or 23F. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 23B, 23D, or 23F while still encoding a protein that maintains its Adrenal secretory serine protease -like activities and physiological functions, or a  
30 functional fragment thereof. In the mutant or variant protein, up to about 55 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that these Adrenal secretory serine protease-like proteins (NOV23) is a member of a "Adrenal secretory serine protease family".

Therefore, the NOV23 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV23 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Von Hippel-Lindau (VHL) syndrome, cirrhosis, transplantation, endometriosis, fertility, anemia, ataxia-telangiectasia, autoimmune disease, hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, allergies, immunodeficiencies, graft versus host disease (GVHD), lymphoedema, muscular dystrophy, Lesch-Nyhan syndrome, myasthenia gravis, and/or other diseases and pathologies.

NOV23 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV23 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV23 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV24

NOV24 includes two novel parchorin-like proteins disclosed below. The disclosed sequences have been named NOV24a and NOV24b.

#### NOV24a

A disclosed NOV24a nucleic acid of 2091 nucleotides (also referred to as CG56455-01) encoding a novel parchorin-like protein is shown in Table 24A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 7-9 and ending with a TGA codon at nucleotides 2080-2082. The start and stop codons are shown in bold in Table 24A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 24A. NOV24a nucleotide sequence (SEQ ID NO:103).**

In a search of public sequence databases, the NOV24a nucleic acid sequence, located on chromosome 21, has 1347 of 1897 bases (71%) identical to a gb:GENBANK-

ID:AB035520|acc:AB035520.1 mRNA from *Oryctolagus cuniculus* (*Oryctolagus cuniculus* mRNA for parchorin, complete cds) ( $E = 2.4e^{-175}$ ).

A disclosed NOV24a polypeptide (SEQ ID NO:104) encoded by SEQ ID NO:103 has 691 amino acid residues and is presented in Table 24B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV24a has no signal peptide and is likely to be localized to the nucleus with a certainty of 0.3000. Alternatively, NOV24a may also localize to the mitochondrial matrix space with a certainty of 0.1000, or to the lysosome (lumen) with a certainty of 0.1000.

**Table 24B. Encoded NOV24a protein sequence (SEQ ID NO:104).**

A search of sequence databases reveals that the NOV24a amino acid sequence has 414 of 655 amino acid residues (63%) identical to, and 453 of 655 amino acid residues (69%) similar to, the 637 amino acid residue ptnr:SPTREMBL-ACC:Q9N2G5 protein from

5 *Oryctolagus cuniculus* (Rabbit) (Parchorin) ( $E = 2.5e^{-182}$ ).

NOV24a is predicted to be expressed in at least the following tissues: brain, lung, and kidney. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

10 In addition, the sequence is predicted to be expressed in gastric parietal cells, choroid plexus, salivary duct, lacrimal gland, kidney, airway epithelia and chorioretinal epithelia because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:AB035520|acc:AB035520.1) a closely related *Oryctolagus cuniculus* mRNA for parchorin, complete cds homolog.

#### 15 NOV24b

A disclosed NOV24b nucleic acid of 859 nucleotides (also referred to as CG56455-02) encoding a novel parchorin-like protein is shown in Table 24C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 1-3 and ending with a TGA codon at nucleotides 853-855. The start and stop codons are shown in bold in Table 24A, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV24b nucleic acid sequence, located on the q22.12 region of chromosome 21, has 741 of 847 bases (87%) identical to a parchorin mRNA from *oryctolagus cuniculus* gb accno AB035520.1 ( $E = 3.2e^{-140}$ ).

25 A disclosed NOV24b polypeptide (SEQ ID NO:106) encoded by SEQ ID NO:105 has 284 amino acid residues and is presented in Table 24D using the one-letter amino acid code.

Signal P, Psort and/or Hydropathy results predict that NOV24b has no signal peptide and is likely to be localized to the nucleus with a certainty of 0.3000. Alternatively, NOV24b may also localize to the mitochondrial matrix space with a certainty of 0.1000, or to the lysosome (lumen) with a certainty of 0.1000.

A search of sequence databases reveals that the NOV24b amino acid sequence has 255 of 281 amino acid residues (90%) identical to, and 263 of 281 amino acid residues (93%) similar to, the 637 amino acid residue ptnr:SPTREMBL-ACC:Q9N2G5 protein from *Oryctolagus cuniculus* (Rabbit) (Parchorin) ( $E = 1.6e^{-134}$ ).

10

NOV24b disclosed in this invention is predicted to be expressed in at least the following tissues: heart, placenta, skeletal muscle, stomach, and lung.

The disclosed NOV24a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 24E.

15

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 24F. In the ClustalW alignment of the NOV24 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

The gene of invention encodes a homolog of parchorin, a new member of the intracellular chloride channel family. Parchorin was discovered as a 120 kDa phosphoprotein in gastric parietal cells (Urushidani et al., J Membr Biol. 1999 Apr 1;168(3):209-20). Subsequent analysis revealed that this protein had significant homology to the family of intracellular chloride channels, especially in the C terminal domain (Nishizawa et al., J Biol Chem 2000 Apr 14;275(15):11164-73). However, unlike other members of this family, parchorin exists mainly in the cytoplasm and translocated to the plasma membrane upon stimulation of chloride ion efflux. In addition, parchorin shows only two hydrophobic domains relative to the ten to twelve domains seen in other intracellular chloride channels. Tissue expression of parchorin in the rabbit is enhanced in cells that secrete water, like parietal cells, choroid plexus, salivary duct, lacrimal gland, kidney, airway epithelia, and chorioretinal epithelia. It is therefore thought that this protein plays a critical role in these tissues, possibly by modulating chloride ion transport.

Intracellular chloride channels have diverse roles within cells, such as volume regulation, acidification of intracellular vesicles, vectorial transepithelial chloride transport and regulation of cellular excitability (Jentsch et al., Pflugers Arch 1999 May;437(6):783-95). Loss of function mutations affecting three different members of this family lead to three human inherited diseases: myotonia congenita, Dent's disease, and Bartter's syndrome. In addition, a mouse knockout model involving a member of this family has been generated that mimics diabetes insipidus (Matsumura et al., Nat Genet 1999 Jan;21(1):95-8).

It is likely, therefore, that the protein of invention participates in physiological functions similar to those of other members of the intracellular chloride channel family, particularly parchorin.

The disclosed NOV24 nucleic acid of the invention encoding a Parchorin-like protein includes the nucleic acids whose sequences are provided in Table 24A or 24C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 24A or 24C while still encoding a

protein that maintains its Adrenal secretory serine protease -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally  
5 includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense  
10 binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 37 percent of the bases may be so changed.

The disclosed NOV24 protein of the invention includes the Parchorin -like protein whose sequence is provided in Table 24B or 24D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown  
15 in Table 24B or 24D while still encoding a protein that maintains its Adrenal secretory serine protease -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 40 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

20 The above disclosed information suggests that this Parchorin -like protein (NOV24) is a member of a "Parchorin family". Therefore, the NOV24 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug  
25 target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV24 nucleic acids and proteins of the invention are useful in potential  
30 therapeutic applications implicated in Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, stroke, tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral disorders, addiction, anxiety, pain, neurodegeneration, systemic lupus erythematosus, autoimmune disease, asthma, emphysema, scleroderma, allergy, ARDS,

diabetes, autoimmune disease, renal artery stenosis, interstitial nephritis, glomerulonephritis, polycystic kidney disease, systemic lupus erythematosus, renal tubular acidosis, IgA nephropathy, hypercalcaemia, Lesch-Nyhan syndrome, cancer, trauma, bacterial/viral/parasitic infection, tissue degeneration, and/or other diseases and pathologies.

5 NOV24 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV24 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV24 protein has multiple hydrophilic  
10 regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV25

15 A disclosed NOV25 nucleic acid of 1123 nucleotides (also referred to as CG56457-01) encoding a novel protein phosphatase-like protein is shown in Table 25A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 60-62 and ending with a TGA codon at nucleotides 768-770. The start and stop codons are shown in bold in Table 25A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 25A. NOV25 nucleotide sequence (SEQ ID NO:107).**

In a search of public sequence databases, the NOV25 nucleic acid sequence, located on chromosome 20, has 324 of 505 bases (64%) identical to a gb:GENBANK-ID:AF165519|acc:AF165519.1 mRNA from *Homo sapiens* (mitogen-activated protein kinase phosphatase x (MKPX) mRNA, complete cds) ( $E = 2.3e^{-31}$ ).

A disclosed NOV25 polypeptide (SEQ ID NO:108) encoded by SEQ ID NO:107 has 236 amino acid residues and is presented in Table 25B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV25 has no signal peptide and is likely to be localized to the cytoplasm with a certainty of 0.6500. Alternatively, NOV25 may also localize to the lysosome (lumen) with a certainty of 0.1805, to the mitochondrial matrix space with a certainty of 0.1000, or to the plasma membrane with a certainty of 0.1000.

**Table 25B. Encoded NOV25 protein sequence (SEQ ID NO:108).**

A search of sequence databases reveals that the NOV25 amino acid sequence has 91 of 169 amino acid residues (53%) identical to, and 125 of 169 amino acid residues (73%) similar to, the 184 amino acid residue ptnr:SPTREMBL-ACC:Q9NRW4 protein from *Homo sapiens* (Human) (Mitogen-Activated Protein Kinase Phosphatase X) ( $E = 7.3e^{-50}$ ).

NOV25 is predicted to be expressed in at least brain, testis, exocrine pancreas, adipose, bone, peripheral blood, salivary glands, spinal cord, thyroid. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources and/or RACE sources.

In addition, the sequence is predicted to be expressed in hematopoietic stem cells because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:AF165519|acc:AF165519.1) a closely related *Homo sapiens* mitogen-activated protein kinase phosphatase x (MKPX) mRNA, complete cds homolog.

The disclosed NOV25 polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 25C.

**Table 25C. BLAST results for NOV25**

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 25D. In the ClustalW alignment of the NOV25 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

The gene of invention is a member of the family of dual specificity protein phosphatases (DSPs; Martell et al., Mol Cells 1998 Feb 28;8(1):2-11). DSPs recognize either Ser/Thr or Tyr moieties as targets for dephosphorylation. These enzymes regulate mitogenic signal transduction and can thereby regulate the cell cycle. Some members of this family are effective tumor suppressors, for example, PTEN. PTEN is required during embryonic development and later in life, and mutations in this gene give rise to different kinds of

inherited and sporadic cancers (Eng, Recent Prog Horm Res 1999;54:441-52; discussion 453). In *Drosophila*, members of the DSP family, such as puckered, have important roles in development (Martin-Blanco et al., Genes Dev 1998 Feb 15;12(4):557-70). The crystal structure of one member of the DSP family has been elucidated (Yuvaniyama et al., Science 1996 May 31;272(5266):1328-31) and this family has been successfully targeted for small molecule drug development (Ducruet et al., Bioorg Med Chem 2000 Jun;8(6):1451-66). In addition, overexpression of a DSP has been demonstrated to be a potential therapy for cardiac hypertrophy (Bueno et al., Circ Res 2001 Jan 19;88(1):88-96). The gene of invention has greatest homology to a DSP identified in hematopoietic stem/progenitor cells from a patient with myelodysplastic syndromes. It shows the presence of a distinct domain present in all DSPs, which qualifies it as a *bona fide* member of this family. Its localization is predicted to be cytoplasmic, which makes it a good candidate to interact with members of the signal transduction cascade governing the cell cycle.

The disclosed NOV25 nucleic acid of the invention encoding a Protein phosphatase-like protein includes the nucleic acid whose sequence is provided in Table 25A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 25A while still encoding a protein that maintains its Protein phosphatase-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 36 percent of the bases may be so changed.

The disclosed NOV25 protein of the invention includes the Protein phosphatase-like protein whose sequence is provided in Table 25B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 25B while still encoding a protein that maintains its Protein phosphatase-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 48 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Protein phosphatase -like protein (NOV25) is a member of a "Protein phosphatase family". Therefore, the NOV25 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV25 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in for example Von Hippel-Lindau (VHL) syndrome, pancreatitis, obesity, Alzheimer's disease, stroke, tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral disorders, addiction, anxiety, pain, neurodegeneration, psychiatric disorders, metabolic disorders, fertility, hypogonadism, xerostomia, hyperthyroidism, hypothyroidism, cancer, trauma, tissue degeneration, viral/bacterial/parasitic infections, and/or other diseases and pathologies.

NOV25 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV25 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV25 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV26

NOV26 includes two novel GAGE-7-like proteins disclosed below. The disclosed sequences have been named NOV26a and NOV26b.

#### NOV26a

A disclosed NOV26a nucleic acid of 550 nucleotides (also referred to as CG56461-01) encoding a novel GAGE-7-like protein is shown in Table 26A. An open reading frame was

identified beginning with a ATG initiation codon at nucleotides 67-69 and ending with a TAA codon at nucleotides 400-402. The start and stop codons are shown in bold in Table 26A, and the 5' and 3' untranslated regions, if any, are underlined.

5 In a search of public sequence databases, the NOV26a nucleic acid sequence, located on the X chromosome, has 293 of 360 bases (81%) identical to a gb:GENBANK-ID:AF251237|acc:AF251237.1 mRNA from *Homo sapiens* (XAGE-1 mRNA, complete cds) ( $E = 3.6e^{-46}$ ).

A disclosed NOV26a polypeptide (SEQ ID NO:110) encoded by SEQ ID NO:109 has  
 10 111 amino acid residues and is presented in Table 26B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV26a has no signal peptide and is likely to be localized to the mitochondrial matrix space with a certainty of 0.4462. Alternatively, NOV26A may also localize to the nucleus with a certainty of 0.3000, to the mitochondrial inner membrane with a certainty of 0.1347, or to the mitochondrial  
 15 intermembrane space with a certainty of 0.1347.

**Table 26B. Encoded NOV26a protein sequence (SEQ ID NO:110).**

MIWRGRSTYRPRRRSVPPPELIGPMLEPGDEEPQEEPTESRDPAPGQEREEDQGAETQVPDLEADLQE  
 LSQSKTGGECEGNGPDDQGKILPKSEQFKMPEGGDRQPQV

A search of sequence databases reveals that the NOV26a amino acid sequence has 60 of 115 amino acid residues (52%) identical to, and 72 of 115 amino acid residues (62%)  
 20 similar to, the 116 amino acid residue ptrn:SPTREMBL-ACC:Q9UEU5 protein from *Homo sapiens* (Human) (GAGE-7) ( $E = 1.4e^{-23}$ ).

NOV26a is predicted to be expressed in at least placenta. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, and/or RACE sources.

25 NOV26b

In the present invention, the target sequence identified previously, NOV26a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on in silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated NOV26b. This is 100% identical to the previously identified sequence (NOV26a).

A disclosed NOV26b nucleic acid of 494 nucleotides (also referred to as CG56461-02) encoding a novel GAGE-7-like protein is shown in Table 26C. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 67-69 and ending with a TAA codon at nucleotides 400-402. The start and stop codons are shown in bold in Table 26C, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV26b nucleic acid sequence, located on the X chromosome, has 346 of 426 bases (81%) identical to a gb:GENBANK-ID:HSL185E6A|acc:Z68274.1 mRNA from *Homo sapiens* (Human DNA sequence from cosmid L129H7, Huntington's Disease Region, chromosome 4p16.3 contains Pseudogene and CpG island) ( $E = 5.7e^{-53}$ ).

The disclosed NOV26b polypeptide (SEQ ID NO:112) encoded by SEQ ID NO:111 has 111 amino acid residues and is presented in Table 26D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV26b has no signal peptide and is likely to be localized to the mitochondrial matrix space with a certainty of 0.4462. Alternatively, NOV26b may also localize to the nucleus with a certainty of 0.3000, to the mitochondrial inner membrane with a certainty of 0.1347, or to the mitochondrial intermembrane space with a certainty of 0.1347.

**Table 26D. Encoded NOV26b protein sequence (SEQ ID NO:112).**

A search of sequence databases reveals that the NOV26b amino acid sequence has 60 of 115 amino acid residues (52%) identical to, and 72 of 115 amino acid residues (62%) similar to, the 116 amino acid residue ptnr:SPTREMBL-ACC:Q9UEU5 protein from *Homo sapiens* (Human) (GAGE-7) ( $E = 1.4e^{-23}$ ).

NOV26b is predicted to be expressed in at least the following tissues: Placenta, Whole Organism.

The disclosed NOV26a polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 26E.

**Table 26E. BLAST results for NOV26a**

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 26F. In the ClustalW alignment of the NOV26 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

20

25

lymphocytes in melanoma, these results suggest that PAGE-1 and GAGE-7 may be related to prostate cancer progression and may serve as potential targets for novel therapies.

The GAGE-1 gene was identified previously as a gene that codes for an antigenic peptide, YRPRRRY, which was presented on a human melanoma by HLA-Cw6 molecules and recognized by a clone of CTLs derived from the patient bearing the tumor. By screening a  
5 cDNA library from this melanoma, De Backer O, et al. (*Cancer Res* 1999 Jul 1;59(13):3157-65) identified five additional, closely related genes named GAGE-2-6. We report here that further screening of this library led to the identification of two more genes, GAGE-7B and -8. GAGE-1, -2, and -8 code for peptide YRPRRRY. Using another antitumor CTL clone  
10 isolated from the same melanoma patient, they identified antigenic peptide, YYWPRRRY, which is encoded by GAGE-3, -4, -5, -6, and -7B and which is presented by HLA-A29 molecules. Genomic cloning of GAGE-7B showed that it is composed of five exons. Sequence alignment showed that an additional exon, which is present only in the mRNA of GAGE-1, has been disrupted in gene GAGE-7B by the insertion of a long interspersed repeated element  
15 retroposon. These GAGE genes are located in the p11.2-p11.4 region of chromosome X. They are not expressed in normal tissues, except in testis, but a large proportion of tumors of various histological origins express at least one of these genes. Treatment of normal and tumor cultured cells with a demethylating agent, azadeoxycytidine, resulted in the transcriptional activation of GAGE genes, suggesting that their expression in tumors results from a  
20 demethylation process.

The disclosed NOV26 nucleic acid of the invention encoding a GAGE-7 -like protein includes the nucleic acid whose sequence is provided in Table 26A, 26C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 26A or 26C while still encoding a  
25 protein that maintains its GAGE-7 -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes  
30 nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense

binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 19 percent of the bases may be so changed.

The disclosed NOV26 protein of the invention includes the GAGE-7 -like protein whose sequence is provided in Table 26B or 26D. The invention also includes a mutant or  
5 variant protein any of whose residues may be changed from the corresponding residue shown in Table 26B or 26D while still encoding a protein that maintains its GAGE-7 -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 28 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or  
10 (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this GAGE-7 -like protein (NOV26) is a member of a "GAGE-7 family". Therefore, the NOV26 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications  
15 for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

20 The NOV26 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in fertility disorders, cancer, trauma, tissue degeneration, viral/bacterial/parasitic infections, and/or other diseases and pathologies.

NOV26 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV26 substances for use in  
25 therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV26 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in  
30 understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV27

NOV27 includes three novel sodium - glucose cotransporter -like proteins disclosed below. The disclosed sequences have been named NOV27a, NOV27b, and NOV27c.

## NOV27a

A disclosed NOV27a nucleic acid of 1914 nucleotides (also referred to as CG56645-01) encoding a novel sodium - glucose cotransporter-like protein is shown in Table 27A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 51-53 and ending with a TGA codon at nucleotides 1839-1841. The start and stop codons are shown in bold in Table 27A, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV27a nucleic acid sequence, located on chromosome 17, has 1598 of 1838 bases (86%) identical to a gb:GENBANK-  
 10 ID:OCU08813|acc:U08813.1 mRNA from *Oryctolagus cuniculus* (*Oryctolagus cuniculus* Na<sup>+</sup>/glucose cotransporter-related protein mRNA, complete cds) (E = 2.6e<sup>-309</sup>).

A disclosed NOV27a polypeptide (SEQ ID NO:114) encoded by SEQ ID NO:113 has 596 amino acid residues and is presented in Table 27B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV27A has a signal peptide and is  
 15 likely to be localized to the plasma membrane with a certainty of 0.8200. Alternatively, NOV27a may also localize to the endoplasmic reticulum (membrane) with a certainty of 0.6850, to the Golgi body with a certainty of 0.4600, or to the enoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV27A is between positions 42 and 43: CRA-SR.

**Table 27B. Encoded NOV27a protein sequence (SEQ ID NO:114).**

A search of sequence databases reveals that the NOV27a amino acid sequence has 531 of 596 amino acid residues (89%) identical to, and 559 of 596 amino acid residues (93%) similar to, the 597 amino acid residue ptnr:SPTREMBL-ACC:Q28610 protein from *Oryctolagus cuniculus* (Rabbit) (Na<sup>+</sup>/Glucose Cotransporter-Related Protein) ( $E = 1.1e^{-289}$ ).

NOV27a is predicted to be expressed in at least heart and kidney. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, and/or RACE sources.

In addition, the sequence is predicted to be expressed in the following tissues because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:OCU08813|acc:U08813.1) a closely related *Oryctolagus cuniculus* Na<sup>+</sup>/glucose cotransporter-related protein mRNA, complete cds homolog.

#### NOV27b

In the present invention, the target sequence identified previously, NOV27a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on in silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea,

uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated NOV27b. This differs from the previously identified sequence (NOV27a) in having 16 extra internal amino acids.

A disclosed NOV27b nucleic acid of 1912 nucleotides (also referred to as CG56645-02 encoding a novel sodium - glucose cotransporter-like protein is shown in Table 27C. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 35-37 and ending with a TGA codon at nucleotides 1871-1873. The start and stop codons are shown in bold in Table 27C, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 27C. NOV27b nucleotide sequence (SEQ ID NO:115).**

The homology between these and other sequences is shown graphically in the  
ClustalW analysis shown in Table 27H. In the ClustalW alignment of the NOV27 protein, as  
10 well as all other ClustalW analyses herein, the black outlined amino acid residues indicate  
regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or  
functional properties), whereas non-highlighted amino acid residues are less conserved and  
can potentially be altered to a much broader extent without altering protein structure or  
function.

The gene of invention codes for a human ortholog of a rabbit sodium-glucose cotransporter (SGLT) and belongs to the large family of SGLTs that has been described to date. The rabbit gene is expressed in the kidney (Pajor, Biochim Biophys Acta 1994 Sep 14;1194(2):349-51), and the novel gene described herein is expressed in the heart in addition to the kidney. It shows the characteristic sodium-solute symporter protein motif shared by members of the SGLT family.

SGLTs are critical in the maintenance of glucose homeostasis in the body, in a variety of tissues. Inhibitors of SGLTs are being studied in the treatment of diabetes. Treatment of

Zucker diabetic fatty rats with the SGLT inhibitor T-1095 lowers both fed and fasted blood glucose levels to near-normal levels (Nawano et al., Am J Physiol Endocrinol Metab 2000 Mar;278(3):E535-43). In streptozotocin-induced diabetic rats, T-1095 also exerts an antihyperglycemic effect which is nullified by nephrectomy, indicating that the drug acts  
5 through inhibition of renal SGLTs rather than intestinal ones (Oku et al., Biol Pharm Bull 2000 Dec;23(12):1434-7) In addition, SGLT-1 seems to have a role in mammalian renal tubulogenesis (Yang et al., Am J Physiol Renal Physiol 2000 Oct;279(4):F765-77).

The disclosed NOV27 nucleic acid of the invention encoding a Sodium - Glucose Cotransporter -like protein includes the nucleic acid whose sequence is provided in Table 27A,  
10 27C, 27E or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 27A, 27C, or 27E while still encoding a protein that maintains its Sodium - Glucose Cotransporter -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described,  
15 including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least  
20 in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 14 percent of the bases may be so changed.

The disclosed NOV27 protein of the invention includes the Sodium - Glucose  
25 Cotransporter -like protein whose sequence is provided in Table 27B, 30D, or 30F. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 27B, 27D, or 27F while still encoding a protein that maintains its Sodium - Glucose Cotransporter -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 42  
30 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Sodium - Glucose Cotransporter -like protein (NOV27) is a member of a "Sodium - Glucose Cotransporter family". Therefore,

the NOV27 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug  
5 targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV27 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in diabetes, obesity, hypertension, cardiomyopathy,  
10 atherosclerosis, congenital heart defects, aortic stenosis, atrial septal defect (ASD), atrioventricular (A-V) canal defect, ductus arteriosus, pulmonary stenosis, subaortic stenosis, ventricular septal defect (VSD), valve diseases, tuberous sclerosis, scleroderma, transplantation, autoimmune disease, renal artery stenosis, interstitial nephritis, glomerulonephritis, polycystic kidney disease, systemic lupus erythematosus, renal tubular  
15 acidosis, IgA nephropathy, hypercalcaemia, Lesch-Nyhan syndrome, cancer, tissue degeneration, diabetic nephropathy, microvascular and macrovascular disease, and/or other diseases and pathologies.

NOV27 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV27 substances for use in  
20 therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV27 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in  
25 understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV28

A disclosed NOV28 nucleic acid of 1560 nucleotides (also referred to as CG56185-01) encoding a MYD-1-like protein is shown in Table 28A. An open reading frame was identified  
30 beginning with a ATG initiation codon at nucleotides 31-33 and ending with a TGA codon at nucleotides 1537-1539. The start and stop codons are shown in bold in Table 28A, and the 5' and 3' untranslated regions, if any, are underlined.

Table 28A. NOV28 nucleotide sequence (SEQ ID NO:119).

In a search of public sequence databases, the NOV28 nucleic acid sequence, located on chromosome 22, has 1466 of 1544 bases (94%) identical to a gb:GENBANK-

ID:HSSIRPALP|acc:Y10375.1 mRNA from *Homo sapiens* (*H.sapiens* mRNA for SIRP-alpha1) ( $E = 7.4e^{-310}$ ).

The disclosed NOV28 polypeptide (SEQ ID NO:120) encoded by SEQ ID NO:119 has 503 amino acid residues and is presented in Table 28B using the one-letter amino acid code.

Signal P, Psort and/or Hydropathy results predict that NOV28 has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.4600. Alternatively,

NOV28 may also localize to the endoplasmic reticulum (membrane) with a certainty of 0.1000, to the endoplasmic reticulum (lumen) with a certainty of 0.1000, or extracellularly with a certainty of 0.1000. The most likely cleavage site for NOV28 is between positions 30 and 31: VAG-EE.

Table 28B. Encoded NOV28 protein sequence (SEQ ID NO:120).

A search of sequence databases reveals that the NOV28 amino acid sequence has 458 of 503 amino acid residues (91%) identical to, and 475 of 503 amino acid residues (94%) similar to, the 503 amino acid residue ptnr:SPTREMBL-ACC:P78324 protein from *Homo*

*sapiens* (Human) (Protein Tyrosine Phosphatase, Non-Receptor Type Substrate 1 Precursor (Shp Substrate-1) (Inhibitory Receptor Shps-1) (Shps-1) (Signal- Regulatory Protein Alpha-1) (SIRP-Alpha1) (MYD-1 Antigen)) ( $E = 5.7e^{-247}$ ).

NOV28 is predicted to be expressed in at least myeloid, macrophages, Adrenal Gland/Suprarenal gland, Bone Marrow, Brain, Whole Organism. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, the sequence is predicted to be expressed in myeloid and macrophages because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:HSSIRPALP| acc: Y10375.1) a closely related *H.sapiens* mRNA for SIRP-alpha1 homolog.

The disclosed NOV28 polypeptide has homology to the amino acid sequences shown in the BLASTP data listed in Table 28C.

| Table 28C. BLAST results for NOV28                |                                                                                                                   |                |                   |                   |        |

15

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 28D. In the ClustalW alignment of the NOV28 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

20

Protein tyrosine phosphatases (PTPases), such as SHP-1 and SHP-2, that contain Src  
homology 2 (SH2) domains play important roles in growth factor and cytokine signal  
transduction pathways. A protein of approximately 115 to 120 kDa that interacts with SHP-1  
and SHP-2 was purified from v-src-transformed rat fibroblasts (SR-3Y1 cells), and the  
corresponding cDNA was cloned. The predicted amino acid sequence of the encoded protein,  
termed SHPS-1 (SHP substrate 1), suggests that it is a glycosylated receptor-like protein with  
three immunoglobulin-like domains in its extracellular region and four YXX(L/V/I) motifs,  
potential tyrosine phosphorylation and SH2-domain binding sites, in its cytoplasmic region.  
Various mitogens, including serum, insulin, and lysophosphatidic acid, or cell adhesion  
induced tyrosine phosphorylation of SHPS-1 and its subsequent association with SHP-2 in  
cultured cells. Thus, SHPS-1 may be a direct substrate for both tyrosine kinases, such as the  
insulin receptor kinase or Src, and a specific docking protein for SH2-domain-containing  
PTPases. In addition, we suggest that SHPS-1 may be a potential substrate for SHP-2 and may  
function in both growth factor- and cell adhesion-induced cell signaling. (Fujioka et al. Mol  
Cell Biol. 1996 Dec;16(12):6887-99.)

The rat OX41 antigen is a cell surface protein containing three immunoglobulin  
superfamily domains and intracellular immunoreceptor tyrosine-based inhibitory motifs  
(ITIM). It is a homologue of the human signal-regulatory protein (SIRP) also known as SHPS-  
1, BIT or MFR. Cell activation-induced phosphorylation of the intracellular ITIM motifs  
induces association with the tyrosine phosphatases SHP-1 and SHP-2. To identify the  
physiological OX41 ligand, recombinant OX41-CD4d3+4 fusion protein was coupled to  
fluorescent beads to produce a multivalent cell binding reagent. The OX41-CD4d3+4 beads  
bound to thymocytes and concanavalin A-stimulated splenocytes. This interaction was blocked  
by the monoclonal antibody (mAb) OX101. Affinity chromatography with OX101 mAb and  
peptide sequencing revealed the rat SIRP ligand to be CD47 (integrin-associated protein). A  
direct interaction between human SIRP and human CD47 was demonstrated using purified  
recombinant proteins and surface plasmon resonance ruling out the involvement of other  
proteins known to be associated with CD47. The affinity of the SIRP/CD47 interaction was  
K(d) approximately 8 microM at 37 degrees C with a k(off) >= 2.1 s(-1). The membrane-distal  
SIRP V-like domain was sufficient for binding to CD47. (Vernon-Wilson EF, et al. Eur J  
Immunol. 2000 Aug;30(8):2130-7.)

The transmembrane glycoprotein SHPS-1 binds the protein tyrosine phosphatase SHP-2 and serves as its substrate. Although SHPS-1 has been implicated in growth factor- and cell adhesion-induced signaling, its biological role has remained unknown. Fibroblasts homozygous for expression of an SHPS-1 mutant lacking most of the cytoplasmic region of this protein exhibited increased formation of actin stress fibers and focal adhesions. They spread more quickly on fibronectin than did wild-type cells, but they were defective in subsequent polarized extension and migration. The extent of adhesion-induced activation of Rho, but not that of Rac, was also markedly reduced in the mutant cells. Activation of the Ras-extracellular signal-regulated kinase signaling pathway and of c-Jun N-terminal kinases by growth factors was either unaffected or enhanced in the mutant fibroblasts. These results demonstrate that SHPS-1 plays crucial roles in integrin-mediated cytoskeletal reorganization, cell motility and the regulation of Rho, and that it also negatively modulates growth factor-induced activation of mitogen-activated protein kinases. (Inagaki, A. et al., EMBO J. 2000 Dec 15;19(24):6721-31.)

Machida K. et al. (Oncogene. 2000 Mar 23;19(13):1710-8.) investigated the effect of cell transformation by v-src on the expression and tyrosine phosphorylation of SHPS-1, a putative docking protein for SHP-1 and SHP-2. They found that transformation by v-src virtually inhibited the SHPS-1 expression at mRNA level. While nontransforming Src kinases including c-Src, nonmyristoylated forms of v-Src had no inhibitory effect on SHPS-1 expression, transforming Src kinases including wild-type v-Src and chimeric mutant of c-Src bearing v-Src SH3 substantially suppressed the SHPS-1 expression. In cells expressing temperature sensitive mutant of v-Src, suppression of the SHPS-1 expression was temperature-dependent. In contrast, tyrosine phosphorylation of SHPS-1 was rather activated in cells expressing c-Src or nonmyristoylated forms of v-Src. SHPS-1 expression in SR3Y1 was restored by treatment with herbimycin A, a potent inhibitor of tyrosine kinase, or by the expression of dominant negative form of Ras. Contrary, active form of Mek1 markedly suppressed SHPS-1 expression. Finally, overexpression of SHPS-1 in SR3Y1 led to the drastic reduction of anchorage independent growth of the cells. Taken together, their results suggest that the suppression of SHPS-1 expression is a pivotal event for cell transformation by v-src, and the Ras-MAP kinase cascade plays a critical role in the suppression.

SHPS-1 (SH2-domain bearing protein tyrosine phosphatase (SHP) substrate-1), a member of the inhibitory-receptor superfamily that is abundantly expressed in macrophages and neural tissue, appears to regulate intracellular signaling events downstream of receptor protein-tyrosine kinases and integrin-extracellular matrix molecule interactions. To investigate

the function of SHPS-1 in a hematopoietic cell line, SHPS-1 was expressed in Ba/F3 cells, an IL-3-dependent pro-B-cell line that lacks endogenous SHPS-1 protein. Interestingly, expression of either SHPS-1, or a mutant lacking the intracellular domain of SHPS-1 (DeltaCT SHPS-1), resulted in the rapid formation of macroscopic Ba/F3 cell aggregates. As the integrin-associated protein/CD47 was shown to be a SHPS-1 ligand in neural cells, Babic, J. et al. (J Immunol. 2000 Apr 1;164(7):3652-8.) investigated whether CD47 played a role in the aggregation of SHPS-1-expressing Ba/F3 cells. In support of this idea, aggregate formation was inhibited by an anti-CD47 Ab. Furthermore, erythrocytes from control, but not from CD47-deficient mice, were able to form rosettes on SHPS-1-expressing Ba/F3 cells. Because erythrocytes do not express integrins, this result suggested that SHPS-1-CD47 interactions can take place in the absence of a CD47-integrin association. They also present evidence that the amino-terminal Ig domain of SHPS-1 mediates the interaction with CD47. Although SHPS-1-CD47 binding likely triggers bidirectional intracellular signaling processes, these results demonstrate that this interaction can also mediate cell-cell adhesion.

Inhibitory immunoreceptors downregulate signaling by recruiting Src homology 2 (SH2) domain-containing tyrosine and/or lipid phosphatases to activating receptor complexes [1]. There are indications that some inhibitory receptors might also perform other functions [2] [3]. In adherent macrophages, two inhibitory receptors, SHPS-1 and PIR-B, are the major proteins binding to the tyrosine phosphatase SHP-1. SHPS-1 also associates with two tyrosine-phosphorylated proteins (pp55 and pp130) and a protein tyrosine kinase [4]. Here, Timms, JF. et al. (Curr Biol. 1999 Aug 26;9(16):927-30.) have identified pp55 and pp130 as the adaptor molecules SKAP55hom/R (Src-kinase-associated protein of 55 kDa homologue) and FYB/SLAP-130 (Fyn-binding protein/SLP-76-associated protein of 130 kDa), respectively, and the tyrosine kinase activity as PYK2. Two distinct SHPS-1 complexes were formed, one containing SKAP55hom/R and FYB/SLAP-130, and the other containing PYK2. Recruitment of FYB/SLAP-130 to SHPS-1 required SKAP55hom/R, whereas PYK2 associated with SHPS-1 independently. Formation of both complexes was independent of SHP-1 and tyrosine phosphorylation of SHPS-1. Finally, tyrosine phosphorylation of members of the SHPS-1 complexes was regulated by integrin-mediated adhesion. Thus, SHPS-1 provides a scaffold for the assembly of multi-protein complexes that might both transmit adhesion-regulated signals and help terminate such signals through SHP-1-directed dephosphorylation. Other inhibitory immunoreceptors might have similar scaffold-like functions.

SHPS-1 (or SIRP) is a member of the immunoglobulin (Ig) superfamily abundantly expressed in neurons and other cell types. Within its cytoplasmic domain, it possesses at least

two immunoreceptor tyrosine-based inhibitory motifs, which are targets for tyrosine phosphorylation and mediate the recruitment of SHP-2, an Src homology 2 (SH2) domain-containing protein-tyrosine phosphatase. Since other immunoreceptor tyrosine-based inhibitory motifs-containing receptors have critical roles in the negative regulation of hemopoietic cell functions, the expression of SHPS-1 in cells of hematological lineages was examined. By analyzing a panel of hemopoietic cell lines, evidence was provided that SHPS-1 is abundantly expressed in macrophages and, to a lesser extent, in myeloid cells. No expression was detected in T-cell or B-cell lines. Expression of SHPS-1 could also be documented in normal ex vivo peritoneal macrophages. Further studies showed that SHPS-1 was an efficient tyrosine phosphorylation substrate in macrophages. However, unlike in non-hemopoietic cells, tyrosine-phosphorylated SHPS-1 in macrophages associated primarily with SHP-1 and not SHP-2. Finally, analyses allowed identification of several isoforms of SHPS-1 in mouse cells. In part, this heterogeneity was due to differential glycosylation of SHPS-1. Additionally, it was caused by the production of at least two distinct shps-1 transcripts, coding for SHPS-1 polypeptides having different numbers of Ig-like domains in the extracellular region. Taken together, these findings indicate that SHPS-1 is likely to play a significant role in macrophages, at least partially as a consequence of its capacity to recruit SHP-1. Veillette, A. et al. (J Biol Chem. 1998 Aug 28;273(35):22719-28.)

SHPS-1 is a 120 kDa glycosylated receptor-like protein that contains immunoglobulin-like domains in its extracellular region and four potential tyrosine phosphorylation for SH2 domain binding sites in its cytoplasmic region. Epidermal growth factor (EGF) stimulated the rapid tyrosine phosphorylation of SHPS-1 and subsequent association of SHPS-1 with SHP-2, a protein tyrosine phosphatase containing SH2 domains, in Chinese hamster ovary cells overexpressing human EGF receptors. In the cells overexpressing SHPS-1, the tyrosine phosphorylation of SHPS-1 was more evident than that observed in parent cells. However, overexpression of SHPS-1 alone did not affect the activation of MAP kinase in response to EGF. These results suggest that SHPS-1 may be involved in the recruitment of SHP-2 from the cytosol to the plasma membrane in response to EGF. Copyright 1997 Academic Press. Ochi, F. et al. (Biochem Biophys Res Commun. 1997 Oct 20;239(2):483-7.)

The immune system recognizes invaders as foreign because they express determinants that are absent on host cells or because they lack 'markers of self' that are normally present. Oldenborg et al. (2000) demonstrated that CD47 functions as a marker of self on murine red blood cells. Red blood cells that lack CD47 were rapidly cleared from the bloodstream by splenic red pulp macrophages. CD47 on normal red blood cells prevented this elimination by

binding to the inhibitory receptor signal regulatory protein alpha (SIRP-alpha). Thus, Oldenborg et al. (2000) concluded that macrophages may use a number of nonspecific activating receptors and rely on the presence or absence of CD47 to distinguish self from foreign. Oldenborg et al. (2000) suggested that CD47-SIRP-alpha may represent a potential  
5 pathway for the control of hemolytic anemia.

The disclosed NOV28 nucleic acid of the invention encoding a MYD-1 -like protein includes the nucleic acid whose sequence is provided in Table 28A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 28A while still encoding a protein that maintains  
10 its MYD-1 -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications  
15 include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 6 percent of the  
20 bases may be so changed.

The disclosed NOV28 protein of the invention includes the MYD-1 -like protein whose sequence is provided in Table 28B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 28B while still encoding a protein that maintains its MYD-1 -like activities and physiological  
25 functions, or a functional fragment thereof. In the mutant or variant protein, up to about 27 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this MYD-1 -like protein (NOV28) is a  
30 member of a "MYD-1 family". Therefore, the NOV28 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic

and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV28 nucleic acids and proteins of the invention are useful in potential  
 5 therapeutic applications implicated in epilepsy, eating disorders, schizophrenia, ADD, and cancer; heart disease; inflammation and autoimmune disorders including Crohn's disease, IBD, allergies, rheumatoid and osteoarthritis, inflammatory skin disorders, allergies, blood disorders; psoriasis colon cancer, leukemia AIDS; thalamus disorders; metabolic disorders including diabetes and obesity; lung diseases such as asthma, hemolytic anemia, emphysema,  
 10 cystic fibrosis, and cancer; pancreatic disorders including pancreatic insufficiency and cancer; and prostate disorders including prostate cancer, and/or other diseases and pathologies.

NOV28 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV28 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods  
 15 known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV28 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various  
 20 disorders.

### NOV29

NOV29 includes three novel CRAL-TRIO-like proteins disclosed below. The disclosed sequences have been named NOV29a, NOV29b, and NOV29c.

### NOV29a

25 A disclosed NOV29a nucleic acid of 1327 nucleotides (also referred to as CG56187-01) encoding a CRAL-TRIO-like protein is shown in Table 29A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 16-18 and ending with a TGA codon at nucleotides 1261-1263. The start and stop codons are shown in bold in Table 29A, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV29a nucleic acid sequence, located on chromosome 22, has 935 of 1263 bases (74%) identical to a gb:GENBANK-

ID:RNO132352|acc:AJ132352.1 mRNA from *Rattus norvegicus* (*Rattus norvegicus* mRNA for 45 kDa secretory protein, partial) ( $E = 4.0e^{-132}$ ).

A disclosed NOV29a polypeptide (SEQ ID NO:122) encoded by SEQ ID NO:121 has 415 amino acid residues and is presented in Table 29B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV29a has no signal peptide and is likely to be localized extracellularly with a certainty of 0.6500. Alternatively, NOV29a may also localize to the mitochondrial membrane space with a certainty of 0.1000, to the lysosome (lumen) with a certainty of 0.1000, or to the microbody (peroxisome) with a certainty of 0.0348.

**Table 29B. Encoded NOV29a protein sequence (SEQ ID NO:122).**

A search of sequence databases reveals that the NOV29a amino acid sequence has 387 of 397 amino acid residues (97%) identical to, and 390 of 397 amino acid residues (98%) similar to, the 406 amino acid residue ptrn:SPTREMBL-ACC:Q9UDX3 protein from *Homo sapiens* (Human) (WUGSC:H\_DJ0539M06.4 PROTEIN) ( $E = 7.2e^{-208}$ ).

NOV29a is predicted to be expressed in at least Bone, liver, brain, and prostate. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, the sequence is predicted to be expressed in Bone because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:RNO132352|acc: AJ132352.1) a closely related *Rattus norvegicus* mRNA for 45 kDa secretory protein, partial homolog.

**NOV29b**

A disclosed NOV29b nucleic acid of 1305 nucleotides (also referred to as CG56187-03) encoding a CRAL-TRIO-like protein is shown in Table 29C. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 14-16 and ending with a TGA codon at nucleotides 1262-1264. The start and stop codons are shown in bold in Table 29C, and the 5' and 3' untranslated regions, if any, are underlined.

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 29H. In the ClustalW alignment of the NOV29 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

35 Vitamin E (alpha-tocopherol) is an essential dietary nutrient for humans and animals. The mechanisms involved in cellular regulation as well as in the preferential cellular and tissue accumulation of alpha-tocopherol are not yet well established. We previously reported (Stocker, A., Zimmer, S., Spycher, S. E., and Azzi, A. (1999) IUBMB Life 48, 49-55) the

identification of a novel 46-kDa tocopherol-associated protein (TAP) in the cytosol of bovine liver. Here, we describe the identification, the molecular cloning into *Escherichia coli*, and the in vitro expression of the human homologue of bovine TAP, hTAP. This protein appears to belong to a family of hydrophobic ligand binding proteins, which have the CRAL (cis-retinal binding motif) sequence in common. By using a biotinylated alpha-tocopherol derivative and the IASys resonant mirror biosensor, the purified recombinant protein was shown to bind tocopherol at a specific binding site with  $K(d) 4.6 \times 10(-7)$  m. Northern analyses showed that hTAP mRNA has a size of approximately 2800 base pairs and is ubiquitously expressed. The highest amounts of hTAP message are found in liver, brain, and prostate. In conclusion, hTAP has sequence homology to proteins containing the CRAL\_TRIO structural motif. TAP binds to alpha-tocopherol and biotinylated tocopherol, suggesting the existence of a hydrophobic pocket, possibly analogous to that of SEC14. Zimmer S. et al. (J Biol Chem. 2000 Aug 18;275(33):25672-80.)

The disclosed NOV29 nucleic acid of the invention encoding a CRAL-TRIO -like protein includes the nucleic acid whose sequence is provided in Table 29A, 29C, 29E or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 29A, 29C, or 29E while still encoding a protein that maintains its CRAL-TRIO -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 26 percent of the bases may be so changed.

The disclosed NOV29 protein of the invention includes the CRAL-TRIO -like protein whose sequence is provided in Table 29B, 29D, or 29F. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 29B, 29D, or 29F while still encoding a protein that maintains its CRAL-TRIO -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 32 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this CRAL-TRIO -like protein (NOV29) is a member of a "CRAL-TRIO family". Therefore, the NOV29 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV29 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in brain disorders including epilepsy, eating disorders, schizophrenia, ADD, and cancer; heart disease; inflammation and autoimmune disorders including Crohn's disease, IBD, allergies, rheumatoid and osteoarthritis, inflammatory skin disorders, allergies, blood disorders; psoriasis colon cancer, leukemia AIDS; thalamus disorders; metabolic disorders including diabetes and obesity; lung diseases such as asthma, emphysema, cystic fibrosis, and cancer; pancreatic disorders including pancreatic insufficiency and cancer; and prostate disorders including prostate cancer, and/or other diseases and pathologies.

NOV29 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV29 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV29 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV30

A disclosed NOV30 nucleic acid of 717 nucleotides (also referred to as CG56191-01) encoding a novel Ryudocan-like protein is shown in Table 30A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 22-24 and ending with a TAG codon at nucleotides 658-660. Putative untranslated regions, if any, found upstream from

the initiation codon and downstream from the termination codon are underlined in Table 30A, and the start and stop codons are in bold letters.

The NOV30 nucleic acid was identified on chromosome 22 and has 553 of 708 bases  
 5 (78%) identical to a gb:GENBANK-ID:HUMRYUDO|acc:D13292.1 mRNA from *Homo sapiens* (mRNA for ryudocan core protein) ( $E = 2.2e^{-82}$ ).

A disclosed NOV30 polypeptide (SEQ ID NO:128) encoded by SEQ ID NO:127 is  
 212 amino acid residues and is presented using the one-letter code in Table 30B. Signal P,  
 Psort and/or Hydropathy results predict that NOV30 contains a signal peptide and is likely to  
 10 be localized in the plasma membrane with a certainty of 0.4600. The most likely cleavage site  
 for NOV30 is between positions 23 and 24: TPT-TP.

The disclosed NOV30 amino acid sequence has 121 of 198 amino acid residues (61%)  
 identical to, and 140 of 198 amino acid residues (70%) similar to, the 202 amino acid residue  
 15 ptrn:SWISSPROT-ACC: P34901 protein from *Rattus norvegicus* (Rat) (Syndecan-4 Precursor  
 (Ryudocan Core Protein)) ( $E = 1.9e^{-51}$ ).

NOV30 is predicted to be expressed in at least myeloid tissue, B-cell lymphoma,  
 including B-cell precursor lymphoblastic leukemia, lymphoplasmacytoid, immunoblastic,  
 lymphocytic/CLL, hairy cell leukemia, large B-cell, mantle-cell, marginal zone and follicular,  
 20 lymphomas, endothelia, Lymphopoietic and bone marrow (BM) plasma cells (PCs). This  
 information was derived by determining the tissue sources of the sequences that were included  
 in the invention including but not limited to SeqCalling sources, Public EST sources,  
 Literature sources, and/or RACE sources.

In addition, NOV30 is predicted to be expressed in the following tissues because of the  
 25 expression pattern of (GENBANK-ID: gb:GENBANK-ID:HUMRYUDO|acc: D13292.1) a

closely related Human mRNA for ryudocan core protein homolog in species *Homo sapiens*: myeloid tissue.

NOV30 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 30C.

20 Table 30E lists the domain description from DOMAIN analysis results against  
NOV30. This indicates that the NOV30 sequence has properties similar to those of other  
proteins known to contain this domain.

gnl|Pfam|pfam01034, Syndecan, Syndecan domain. Syndecans are transmembrane heparin sulfate proteoglycans which are implicated in the binding of extracellular matrix components and growth factors (SEQ ID NO:824)  
CD-Length = 359 residues, 21.7% aligned  
Score = 41.6 bits (96), Expect = 5e-05

Kininogens, the high molecular weight precursor of vasoactive kinins, bind to a wide variety of cells in a specific, reversible, and saturable manner. The cell docking sites have been mapped to domains D3 and D5(H) of kininogens; however, the corresponding cellular acceptor sites are not fully established. To characterize the major cell binding sites for kininogens exposed by the endothelial cell line EA.hy926, intact cells were digested with trypsin and other proteases and found a time- and concentration-dependent loss of (125)I-labeled high molecular weight kininogen (H-kininogen) binding capacity (up to 82%), indicating that proteins are crucially involved in kininogen cell attachment. Cell surface digestion with heparinases similarly reduced kininogen binding capacity (up to 78%), and the combined action of heparinases and trypsin almost eliminated kininogen binding (up to 85%).

suggesting that proteoglycans of the heparan sulfate type are intimately involved. Consistently, inhibitors such as p-nitrophenyl-beta-d-xylopyranoside and chlorate interfering with heparan sulfate proteoglycan biosynthesis reduced the total number of kininogen binding sites in a time- and concentration-dependent manner (up to 67%). *In vitro* binding studies demonstrated that biotinylated H-kininogen binds to heparan sulfate glycosaminoglycans via domains D3 and D5(H) and that the presence of Zn(2+) promotes this association. Cloning and over-expression of the major endothelial heparan sulfate-type proteoglycans syndecan-1, syndecan-2, syndecan-4, and glypican in HEK293t cells significantly increased total heparan sulfate at the cell surface and thus the number of kininogen binding sites (up to 3.3-fold). This gain in kininogen binding capacity was completely abolished by treating transfected cells with heparinases. It was concluded that heparan sulfate proteoglycans on the surface of endothelial cells provide a platform for the local accumulation of kininogens on the vascular lining. This accumulation may allow the circumscribed release of short-lived kinins from their precursor molecules in close proximity to their sites of action (Renne et al., J Biol Chem 2000, 275(43):33688-96).

Lymphopoietic cells require interactions with bone marrow stroma for normal maturation and show changes in adhesion to matrix during their differentiation. Syndecan, a heparan sulfate-rich integral membrane proteoglycan, functions as a matrix receptor by binding cells to interstitial collagens, fibronectin, and thrombospondin. Therefore, it was asked whether syndecan was present on the surface of lymphopoietic cells. In bone marrow, syndecan was only found on precursor B cells. Expression changes with pre-B cell maturation in the marrow and with B-lymphocyte differentiation to plasma cells in interstitial matrices. Syndecan on B cell precursors is more heterogeneous and slightly larger than on plasma cells. Syndecan 1) is lost immediately before maturation and release of B lymphocytes into the circulation, 2) is absent on circulating and peripheral B lymphocytes, and 3) is reexpressed upon their differentiation into immobilized plasma cells. Thus, syndecan is expressed only when and where B lymphocytes associate with extracellular matrix. These results indicate that B cells differentiating *in vivo* alter their matrix receptor expression and suggest a role for syndecan in B cell stage-specific adhesion (Sanderson et al., Cell Regul 1989,1(1):27-35).

Detection of abnormal numbers and/or distribution of bone marrow (BM) plasma cells (PCs) on trephine biopsies can be important in the differential diagnosis of multiple myeloma (MM) and other PC disorders. A variety of immunohistochemical markers can potentially improve the specificity and sensitivity of PC detection on routine histological sections obtained from trephine BM biopsies, but most of them are not completely satisfactory. In one

study, the antibody CD138/B-B4, which is an optimal marker for PC detection on BM aspirates by flow cytometry, was investigated to determine whether it can be used successfully for the identification of PCs also on formalin-fixed, decalcified biopsies. A series of samples including normal BM, MM, monoclonal gammopathies of undetermined significance, and B-cell lymphoma of various types, including B-cell precursor lymphoblastic leukemia, lymphoplasmacytoid, immunoblastic, lymphocytic/CLL, hairy cell leukemia, large B-cell, mantle-cell, marginal zone and follicular lymphomas, have been investigated for CD138 expression using a sensitive immunohistochemical technique. Within the BM microenvironment, CD138 was characterized by excellent sensitivity and specificity. Virtually all normal and neoplastic PCs expressed clear-cut membrane CD138 immunostaining, whereas all other cell types did not. All cases of MM, including plasmablastic and leukemic cases, showed strong immunoreactivity. Conversely, all B-cell lymphomas, including all cases characterized by secretive features, lymphoplasmacytoid, and immunoblastic lymphomas, were completely negative. These results demonstrate that CD138 is a highly sensitive and specific marker that is useful for the rapid and precise localization of normal and neoplastic PCs on routine BM sections. In addition, because of its clear-cut cell membrane localization, CD138 can be used successfully in double-marker immunostaining reactions to evaluate precisely nuclear prognostic markers such as Ki67 and p53 in MMs (Chilosi et al., *Mod Pathol* 1999, 12(12):1101-6).

Monoclonal antibody therapy has emerged as a viable treatment option for patients with lymphoma and some leukemias. It is now beginning to be investigated for treatment of multiple myeloma. There are relatively few surface antigens on the plasma cells that are suitable for antibody-directed treatment. Possible molecules include HM1.24, CD38, ICAM-1 (CD54), CD40, CD45, CD20, and syndecan 1. There is now some clinical experience with anti-CD38 antibody in lymphoma and myeloma. However, to date, there has been minimal clinical activity observed. Additional antibodies are entering clinical trials. A new approach involves the generation of an anti-CD38 single-chain variable fragment (scFv) construct that acts as the carrier of a toxin gene instead of being conjugated directly to the toxin itself. It is hoped that expression of the toxin by CD38+ plasma cells will promote suicide of the malignant cells without affecting normal cells or generating an immunologic response to the toxin. Ongoing clinical trials are also attempting to target B-cell antigens such as CD20. Although CD20 is present only on 20% of myeloma cells, it may be present on myeloma precursor cells. This treatment has met with success in follicular lymphoma and is now being evaluated in clinical trials in both Europe and the United States for myeloma. Although these

clinical trials are in very early stages, researchers are beginning to understand that antibody therapy can be used not only as a carrier molecule of radioisotopes and toxins, but also as molecules that can trigger tumor cells and promote growth arrest or apoptosis (Maloney et al., Semin Hematol 1999, 36(1 Suppl 3):30-3).

5           The NOV30 nucleic acid of the invention encoding a Ryudocan-like protein includes the nucleic acid whose sequence is provided in Table 30A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 30A while still encoding a protein that maintains its Ryudocan-like activities and physiological functions, or a fragment of such a nucleic acid.

10          The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar

15          phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 22% of the residues may be so changed.

20           The NOV30 protein of the invention includes the Ryudocan-like protein whose sequence is provided in Table 30B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 30B while still encoding a protein that maintains its Ryudocan-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 63 of the bases

25          may be so changed.

          The NOV30 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below and/or other pathologies. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from: brain disorders including epilepsy,

30          eating disorders, schizophrenia, ADD, cancer, heart disease, inflammation and autoimmune disorders including Crohn's disease, IBD, allergies, rheumatoid and osteoarthritis, inflammatory skin disorders, allergies, blood disorders, psoriasis, colon cancer, leukemia, AIDS, thalamus disorders, metabolic disorders including diabetes and obesity, lung diseases such as asthma, myelomas, emphysema, cystic fibrosis, and cancer, pancreatic disorders

including pancreatic insufficiency and cancer, and prostate disorders including prostate cancer and other diseases, disorders and conditions of the like.

NOV30 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV30 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV31

A disclosed NOV31 nucleic acid of 683 nucleotides (also referred to as CG56392-01) encoding a novel Sulfur-rich Keratin-like protein is shown in Table 31A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 46-48 and ending with a TGA codon at nucleotides 652-654. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 31A, and the start and stop codons are in bold letters.

The NOV31 nucleic acid was identified on chromosome 11 and has 654 of 683 bases (95%) identical to a gb:GENBANK-ID:HSA6693|acc:AJ006693.1 mRNA from *Homo sapiens* (UHS KerA gene) ( $E = 3.3e^{-136}$ ).

A disclosed NOV31 polypeptide (SEQ ID NO:130) encoded by SEQ ID NO:129 is 202 amino acid residues and is presented using the one-letter code in Table 31B. Signal P, Psort and/or Hydropathy results predict that NOV31 contains a signal peptide and is likely to be localized to the cytoplasm with a certainty of 0.4500. The most likely cleavage site for a NOV31 peptide is between amino acids 32 and 33: TRT-MG.

**Table 31B. Encoded NOV31 protein sequence (SEQ ID NO:130)**

The disclosed NOV31 amino acid sequence has 158 of 170 amino acid residues (92%) identical to, and 158 of 170 amino acid residues (92%) similar to, the 169 amino acid residue ptrn:SWISSNEW-ACC:P26371 protein from *Homo sapiens* (Human) (Keratin, Ultra High-Sulfur Matrix Protein A (Uhs Keratin A) (Uhs Kera)) ( $E = 1.8e^{-101}$ ).

NOV31 is predicted to be expressed in at least Kidney, Pancreas, Testis and Whole Organism. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, NOV31 is predicted to be expressed in the following tissues because of the expression pattern of (GENBANK-ID:gb:GENBANK-ID:HSA6693|acc:AJ006693.1) a closely related *Homo sapiens* UHS Kera gene homolog in species *Homo sapiens*: Kidney, Pancreas and Testis.

NOV31 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 31C.

**Table 31C. BLAST results for NOV31**

Insulin-like growth factor 1 (IGF-1) mediates many of the actions of growth hormone.

5 Overexpression of IGF-1 has been reported to have endocrine and paracrine/autocrine effects on somatic growth in transgenic mice. To study the paracrine/autocrine effects of IGF-1 in hair follicles, transgenic mice were produced by pronuclear microinjection of a construct containing a mouse ultra-high sulfur keratin (UHS-KER) promoter linked to an ovine IGF-1 cDNA. This UHS-KER promoter has previously been shown to direct expression of a reporter

10 gene to the hair follicles of transgenic mice. Four transgenic mouse lines were established as a result of microinjection of 435 embryos. Transgene expression was found in skin at day 8 and day 15 of age in three of the lines. Progeny tests were carried out by mating two of the transgenic expressing males to nontransgenic females. Mice from one line were all nonexpressors while four of the 12 mice from the other showed integration of the transgene

15 and three expressed transgene IGF-1 mRNA in the skin. Vibrissa growth at 11-21 d of age was significantly greater in transgenic expressors than in their nontransgenic littermates. Specifically, the increase in vibrissa length for transgenics at days 11-16 (20.5%) is approximately 2-fold compared with days 16-21 (11.9%). These results demonstrate that local overexpression of IGF-1 in transgenic mice is capable of stimulating vibrissa growth during

20 the first neonatal hair cycle (Su et al., J Invest Dermatol 1999, 112(2):245-8).

The major histological components of the hair follicle are the hair cortex and cuticle. The hair cuticle cells encase and protect the cortex and undergo a different developmental program to that of the cortex. In one study, the molecular characterization of a set of evolutionarily conserved hair genes which are transcribed in the hair cuticle late in follicle

25 development was reported. Two genes were isolated and characterized, one expressed in the human follicle and one in the sheep follicle. Each gene encodes a small protein of 16 kD, containing greater than 50 cysteine residues, ranging from 31 to 36 mol% cysteine. Their high cysteine content and in vitro expression data identify them as ultra-high-sulfur (UHS) keratin proteins. The predicted proteins are composed almost entirely of cysteine-rich and glycine-rich

30 repeats. Genomic blots reveal that the UHS keratin proteins are encoded by related multigene families in both the human and sheep genomes. Tissue in situ hybridization demonstrates that the expression of both genes is localized to the hair fiber cuticle and occurs at a late stage in fiber morphogenesis (MacKinnon et al., J Cell Biol 1990, 111(6 Pt 1):2587-600).

The NOV31 nucleic acid of the invention encoding a Sulfur-rich Keratin-like protein

35 includes the nucleic acid whose sequence is provided in Table 31A, or a fragment thereof. The

invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 31A while still encoding a protein that maintains its Sulfur-rich Keratin-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 5% of the residues may be so changed.

The NOV31 protein of the invention includes the Sulfur-rich Keratin-like protein whose sequence is provided in Table 31B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 31B while still encoding a protein that maintains its Sulfur-rich Keratin-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 56% of the bases may be so changed.

The NOV31 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below and/or other pathologies. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from: brain disorders including epilepsy, eating disorders, schizophrenia, ADD, cancer, heart disease, inflammation and autoimmune disorders including Crohn's disease, IBD, allergies, rheumatoid and osteoarthritis, inflammatory skin disorders, allergies, blood disorders, psoriasis, colon cancer, leukemia, AIDS, thalamus disorders, metabolic disorders including diabetes and obesity, lung diseases such as asthma, emphysema, cystic fibrosis, and cancer, pancreatic disorders including pancreatic insufficiency and cancer, and prostate disorders including prostate cancer and other diseases, disorders and conditions of the like.

NOV31 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-

NOVX Antibodies" section below. For example the disclosed NOV31 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV32

A disclosed NOV32 nucleic acid of 1575 nucleotides (also referred to as CG56686-01) encoding a novel DNMT1 associated protein-1 (DMAP)-like protein is shown in Table 32A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 94-96 and ending with a TGA codon at nucleotides 1573-1575. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 32A, and the start and stop codons are in bold letters.

The disclosed NOV32 amino acid sequence has 401 of 401 amino acid residues  
 (100%) identical to, and 401 of 401 amino acid residues (100%) similar to, the 467 amino acid  
 residue ptnr:SPTREMBL-ACC:Q9NPF5 protein from *Homo sapiens* (Human) (Hypothetical  
 5 53.0 Kda Protein (Dnmt1 Associated Protein-1) ( $E = 1.3e^{-248}$ ).

NOV32 is predicted to be expressed in at least Adrenal gland, bone marrow, brain -  
 amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus,  
 brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji,  
 mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle,  
 10 small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea and uterus. This  
 information was derived by determining the tissue sources of the sequences that were included  
 in the invention including but not limited to SeqCalling sources, Public EST sources,  
 Literature sources, and/or RACE sources.

NOV32 also has homology to the amino acid sequences shown in the BLASTP data  
 15 listed in Table 32C.

**Table 32C. BLAST results for NOV32**

Methylation of CpG islands is associated with transcriptional silencing and the  
 formation of nuclease-resistant chromatin structures enriched in hypoacetylated histones.  
 Methyl-CpG-binding proteins, such as MeCP2, provide a link between methylated DNA and  
 hypoacetylated histones by recruiting histone deacetylase, but the mechanisms establishing the  
 methylation patterns themselves are unknown. Whether DNA methylation is always causal for  
 the assembly of repressive chromatin or whether features of transcriptionally silent chromatin  
 might target methyltransferase remains unresolved. Mammalian DNA methyltransferases  
 (DNMT) show little sequence specificity *in vitro*, yet methylation can be targeted *in vivo*  
 within chromosomes to repetitive elements, centromeres and imprinted loci. This targeting is  
 frequently disrupted in tumour cells, resulting in the improper silencing of tumour-suppressor  
 genes associated with CpG islands. Robertson et al. (Nat Genet 2000, 25:338-42) have shown  
 that the predominant mammalian DNA methyltransferase, DNMT1, co-purifies with the  
 retinoblastoma (Rb) tumour suppressor gene product, E2F1, and HDAC1 and that DNMT1  
 cooperates with Rb to repress transcription from promoters containing E2F-binding sites.  
 These results establish a link between DNA methylation, histone deacetylase and sequence-  
 specific DNA binding activity, as well as a growth-regulatory pathway that is disrupted in  
 nearly all cancer cells. Recently, Rountree et al. (Nat Genet, 2000, 25:269-77) have shown that  
 the non-catalytic amino terminus of DNMT1 binds to HDAC2 and a new protein, DMAP1 (for  
 DNMT1 associated protein), and can mediate transcriptional repression. DMAP1 has intrinsic  
 transcription repressive activity, and binds to the transcriptional co-repressor TSG101.

DMAP1 is targeted to replication foci through interaction with the far N terminus of DNMT1 throughout S phase, whereas HDAC2 joins DNMT1 and DMAP1 only during late S phase, providing a platform for how histones may become deacetylated in heterochromatin following replication. Thus, DNMT1 not only maintains DNA methylation, but also may directly target, in a heritable manner, transcriptionally repressive chromatin to the genome during DNA replication.

The NOV32 nucleic acid of the invention encoding a DNMT1 associated protein-1 (DMAP)-like protein includes the nucleic acid whose sequence is provided in Table 32A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 32A while still encoding a protein that maintains its DNMT1 associated protein-1 (DMAP)-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 3% of the residues may be so changed.

The NOV32 protein of the invention includes the DNMT1 associated protein-1 (DMAP)-like protein whose sequence is provided in Table 32B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 32B while still encoding a protein that maintains its DNMT1 associated protein-1 (DMAP)-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 9% of the bases may be so changed.

The NOV32 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below and/or other pathologies. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from: cancers such as breast cancer, colorectal cancers, lung cancer, liver cancer, pancreatic cancer, prostate cancer, stomach cancers,

developmental syndromes, Fragile X and Rett and other diseases, disorders and conditions of the like.

NOV32 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV32 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV33

A disclosed NOV33 nucleic acid of 7693 nucleotides (also referred to as CG56688-01) encoding a novel Notch1-like protein is shown in Table 33A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 1-3 and ending with a TAA codon at nucleotides 7669-7671. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 33A, and the start and stop codons are in bold letters.

The NOV33 nucleic acid has 7670 of 7693 bases (99%) identical to a gb:GENBANK-ID:AF308602|acc:AF308602.1 mRNA from *Homo sapiens* (NOTCH 1 (N1) mRNA, complete cds) (E = 0.0).

- 5 A disclosed NOV33 polypeptide (SEQ ID NO:134) encoded by SEQ ID NO:133 is 2556 amino acid residues and is presented using the one-letter code in Table 33B. Signal P, Psort and/or Hydropathy results predict that NOV33 contains a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.4600. The most likely cleavage site for a NOV33 peptide is between amino acids 18 and 19: ALA-AR.

**Table 33B. Encoded NOV33 protein sequence (SEQ ID NO:134)**

The disclosed NOV33 amino acid sequence has 2543 of 2556 amino acid residues (99%) identical to, and 2545 of 2556 amino acid residues (99%) similar to, the 2556 amino acid residue ptrn:TREMBLNEW-ACC:AAG33848 protein from *Homo sapiens* (Human) (Notch 1) (E = 0.0).

NOV33 is predicted to be expressed in at least Adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea and uterus. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, NOV33 is predicted to be expressed in the following tissues because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:AF308602|acc:AF308602.1) a closely related *Homo sapiens* NOTCH 1 (N1) mRNA, complete cds homolog in species *Homo sapiens*: brain.

NOV33 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 33C.

| Table 33C. BLAST results for NOV33              |                                                                                                   |                |                 |                  |        |

Notch is a surface receptor. It transmits signals received from outside the cell to the cell's interior. Notch ligands, such as Delta, Serrate and Scabrous interact with epidermal growth factor repeats contained in Notch's extracellular domain. Notch plays an active role in the differentiation of glial cells and Notch influences the length and organisation of neuronal processes. Several homologs of the Drosophila Notch receptor and its ligands, Delta/Serrate, have been cloned in man. Three human disorders including a neoplasia (a T-cell acute lymphoblastic leukemia/lymphoma), a late onset neurological disease (CADASIL) and a developmental disorder (the Alagille syndrome) are associated with mutations in, respectively, the Notch1, Notch3 and Jagged1 genes, pointing out the broad spectrum of Notch activity in humans (Joutel A, and Tournier-Lasserre E, 1998, Semin Cell Dev Biol, 9:619-25; Frisen J, and Lendahl U, 2001, Bioessays 23:3-7).

In Drosophila, the intracellular domain of Notch binds Suppressor of hairless, a multifunction transcription factor that acts as a signal transducing molecule shuttling between the cytoplasm and the nucleus. A nuclear function has been documented for the mammalian Notch homolog (Lu, 1996), as well as for Drosophila Notch (Struhl and Adachi, 1998, Cell 93:649-60). When Notch is bound by a ligand, a signal is passed across the cell membrane releasing the Suppressor of Hairless protein, freeing this protein to enter the nucleus and assume its role in activating transcription of enhancer of Split complex genes. E(spl)-C proteins act in turn to repress the adoption of neural and other differentiated states. Deltex, an intracellular docking protein, replaces Suppressor of Hairless as Su(H) leaves the site of interaction with the intracellular tail of Notch.

The Notch receptor's function is called neurogenic, but this confusing nomenclature refers to the phenotype established in the absence of functional Notch. Notch's function is to repress the adoption of differentiation by cells that carry the Notch protein. A look at the principle ligand of Notch (Delta) and its function makes the anti-neural function of Notch

more easily understood. Delta is not secreted, but is cell bound. The Delta-Notch interaction serves a cell adhesive function between ligand and receptor bearing cells. The receptor bearing cell is inhibited in assuming a differentiated state, while the ligand bearing cell is free to do so. During neurogenesis, this latter cell delaminates, that is, it migrates out of the epithelial cell layer in which it formerly resided, and assumes the differentiated state of a neuroblast in its new physical location within the developing nervous system. Thus Notch is involved in neurogenesis with respect to cells that bears the ligands for Notch: Delta, Serrate and Scabrous.

Lateral inhibition is one of the major themes of development. The process of lateral inhibition and cell selection is repeated hundreds of times in *Drosophila*, with differentiation that takes place in nearly every kind of tissue. For example, Notch is required to limit the number of neuronal precursors, limit the number of muscle precursors, limit the growth of malpighian tubules, and regulate the growth of the ovary. Notch also functions as receptor for both Serrate and Delta in organizing the dorsal-ventral boundary of the wing. One important target of Serrate and Notch in this context is wingless (Diaz-Benjumea and Cohen, 1995, Development 121:4215-25). Two extreme models can be envisioned for lateral inhibition. The first implicates the Notch pathway in the choice of a single precursor via a negative feedback loop. This process could be random in some cases. The second model postulates that the precursor is pre-determined by some mechanism other than Notch signaling, and that Notch signaling then serves only to mediate mutual, uniform repression of other cells and ensure development of a single precursor. Studies concerning the physical spacing of precursors for the microchaetes of the peripheral nervous system suggest the existence of a regulatory loop under transcriptional control between Notch and its ligand Delta. Activation of Notch leads to repression of the achaete-scute genes, which are themselves known to regulate transcription of Delta; this regulation may perhaps be direct (Seugnet et al., 1997, Dev Biol. 192:585-98). Neuroblast segregation was studied in embryos lacking both the maternal and the zygotic forms of either Notch or Delta. A seven-up-LacZ marker was used to follow neuralization of 5-2 and 7-4 neuroblast groups. In the absence of Notch signaling, the cells with an equivalence group do not enter the neural differentiation pathway simultaneously. Neuralization within a group is progressive with two or three cells segregating early and several more later. This suggests that neural potential is not evenly distributed among these cells. A requirement for transcriptional regulation of Notch and/or Delta during neuroblast segregation in embryos was tested by providing Notch and Delta ubiquitously at uniform levels. Neuroblast segregation occurs normally under conditions of uniform Notch expression, suggesting that transcriptional

regulation of Notch is not necessary for many aspects of development of the larval CNS and PNS. In particular, it is dispensable both before and after neuroblast segregation, implying that it is not a necessary component of neuroblast segregation, per se. Under conditions of uniform Delta expression, a single neuroblast segregates from each proneural group in 80% of the cases; in the remaining 20%, more than one neuroblast segregates from a single group of cells. Thus transcriptional regulation of Delta is largely dispensable, with only a small percentage of multiple neurons segregating in each cluster. Genes such as *achaete*, *scute*, *extramacrochaete*, and *wingless* could be responsible for local differences in proneural activity. Notch signaling would enable all cells to mutually repress one another; only a cell with an elevated neural potential could overcome this repression (Seugnet et al., 1997, Development 124:2015-25).

The development and patterning of the wing in *Drosophila* relies on a sequence of cell interactions molecularly driven by a number of ligands and receptors. Genetic analysis indicates that a receptor encoded by the Notch gene and a signal encoded by the *wingless* gene play a number of interdependent roles in this process and display very strong functional interactions. At certain times and places, during wing development, the expression of *wingless* requires Notch activity and that of its ligands Delta and Serrate. This has led to the proposal that all the interactions between Notch and *wingless* can be understood in terms of this regulatory relationship. This proposal has been tested by analyzing interactions between Delta- and Serrate-activated Notch signaling and Wingless signaling during wing development and patterning. Cell death caused by expressing dominant negative Notch molecules during wing development cannot be rescued by coexpressing *Nintra*. This suggests that the dominant negative Notch molecules cannot only disrupt Delta and Serrate signaling but can also disrupt signaling through another pathway. One possibility is the Wingless signaling pathway, since the cell death caused by expressing dominant negative Notch molecules can be rescued by activating Wingless signaling. Furthermore, the outcome of the interactions between Notch and Wingless signaling differs when Wingless signaling is activated by expressing either Wingless itself or an activated form of the Armadillo. For example, the effect of expressing the activated form of Armadillo with a dominant negative Notch on the patterning of sense organ precursors in the wing resembles the effects of expressing Wingless alone. This result suggests that signaling activated by Wingless leads to two effects: a reduction of Notch signaling and an activation of Armadillo (Brennan, 1999, Curr Biol, 9:707-10).

Expression of a dominant negative Notch molecule (Extracellular Notch or ECN) throughout the developing wing mimics the effects of loss of Notch function. However, *Nintra* cannot rescue the cell death caused by overexpressing ECN. Since *Nintra* provides constitutive

signaling for Delta and Serrate during wing development and the effects of ECN are mediated by the sequestration of extracellular molecules that can interact with Notch, this suggests that the ECN molecule is sequestering extracellular molecules other than Delta and Serrate and attenuating signaling through another pathway. One candidate pathway is the Wingless signaling pathway, since the cell death caused by expressing the ECN can be rescued by activating Wingless signaling. Therefore, it is possible that the ECN molecule is sequestering the Wingless protein. The possibility that Wingless can bind the extracellular domain of Notch is supported by the following results, in particular, by two observations: first, that some of the deleterious effects of ECN can be suppressed by Wingless, but not Wingless signaling in the form of a constitutively active Armadillo molecule; and second, that this interaction requires specific EGF-like repeats of Notch, namely repeats 17-19 and 24-26 but not 10-12. Evidence for a physical interaction between Notch and Wingless has also been provided recently by Wesley (1999, *Mol Cell Biol.* 19:5743-58) who finds that the Wingless protein is enriched in a biopanning assay designed to identify proteins that interact with the extracellular domain of the Notch protein and that Wingless can be immunoprecipitated with Notch from embryo extracts and cultured cells. These experiments also show that the association of Wingless with Notch requires the integrity of a region of Notch centered around EGF-like repeats 24-26 (Wesley, 1999, *Mol Cell Biol.* 19:5743-58) which these experiments indicate are essential for the interactions that are described between Wingless and ECN during wing development and patterning (Brennan et al., 1999, *Curr Biol.* 9:707-10). The interaction of Wingless and Notch signaling that has been observed might also be important during normal neural development. Wingless and Delta have opposite effects during neurogenesis; Wingless promotes while Delta suppresses the development of sense organs. Various experiments suggest that during the segregation of neural precursors a reduction of Notch signaling in the precursors themselves is as important as the Delta-mediated activation of Notch signaling in the surrounding cells. It is possible that, like the activation of Notch by Delta, the suppression of Notch signaling is an active process mediated by the interaction of Wingless and Dishevelled with Notch. If this were the case, since both Delta and Wingless have spatially and temporally regulated patterns of gene expression, their interactions with Notch could contribute to the well-documented bias in the appearance of precursors from clusters of cells with neural potential. This competitive interaction could also account for the observed increases in Wingless signaling associated with reductions in Notch signaling during lateral inhibition (Brennan et al., 1999, *Curr Biol.* 9:707-10; Brennan et al, 1999, *Dev Biol.* 216:210-29).

The NOV33 nucleic acid of the invention encoding a Notch1-like protein includes the nucleic acid whose sequence is provided in Table 33A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 33A while still encoding a protein that maintains its

5 Notch1-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications

10 include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 1% of the residues

15 may be so changed.

The NOV33 protein of the invention includes the Notch1-like protein whose sequence is provided in Table 33B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 33B while still encoding a protein that maintains its Notch1-like activities and physiological functions, or a

20 functional fragment thereof. In the mutant or variant protein, up to about 11% of the bases may be so changed.

The NOV33 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below and/or other pathologies. For example, the compositions of the present invention will

25 have efficacy for treatment of patients suffering from: neoplasia such as T-cell acute lymphoblastic leukemia/lymphoma and mammary carcinomas, a late onset neurological disease like CADASIL and a developmental disorder such as the Alagille syndrome, familial and congenital cholestatic diseases, Hereditary vascular dementia, neurological diseases and other diseases, disorders and conditions of the like.

30 NOV33 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV33 protein have multiple

hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

# 5 NOV34

A disclosed NOV34 nucleic acid of 935 nucleotides (also referred to as CG56715-01) encoding a novel Olfactory Receptor-like protein is shown in Table 34A. An open reading frame was identified beginning with an ACA codon, which codes for the amino acid Threonine, at nucleotides 2-4 and ending with a TGA codon at nucleotides 932-934. Putative  
10 untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 34A, and the start and stop codons are in bold letters.

20 genes, complete cds; HOR5'Beta2 pseudogene, complete sequence; and HOR 5'Beta1 gene,  
complete cds) ( $E = 6.1e^{-50}$ ).

A disclosed NOV34 polypeptide (SEQ ID NO:136) encoded by SEQ ID NO:135 is  
310 amino acid residues and is presented using the one-letter code in Table 34B. Signal P,  
Psort and/or Hydropathy results predict that NOV34 contains a signal peptide and is likely to  
25 be localized to the plasma membrane with a certainty of 0.6000. The most likely cleavage site  
for a NOV34 peptide is between amino acids 36 and 37: IMG-NT.

The disclosed NOV34 amino acid sequence has 160 of 296 amino acid residues (54%) identical to, and 210 of 296 amino acid residues (70%) similar to, the 319 amino acid residue ptrn:TREMBLNEW-ACC:AAG41684 protein from *Mus musculus* (Mouse) (MOR 3'BETA4) (E = 6.3e<sup>-83</sup>).

NOV34 is predicted to be expressed in at least Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

NOV34 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 34C.

G-Protein Coupled Receptor (GPCRs) have been identified as an extremely large family of protein receptors in a number of species. At the phylogenetic level they can be

classified into four major subfamilies. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors. They are likely to be involved in the recognition and transduction of various signals mediated by G-Proteins, hence their name G-Protein Coupled Receptors. The human GPCR genes are generally intron-less and belong to  
5 four gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large family of GPCRs in a number of species. As members of the GPCR family, these receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are  
10 likely to underlie the recognition and G-protein-mediated transduction of odorant signals. Like GPCRs, the ORs they can be expressed in a variety of tissues where they are thought to be involved in recognition and transmission of a variety of signals. The human OR genes are typically intron-less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

15 The NOV34 nucleic acid of the invention encoding a Olfactory Receptor-like protein includes the nucleic acid whose sequence is provided in Table 34A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 34A while still encoding a protein that maintains its Olfactory Receptor-like activities and physiological functions, or a fragment of such a  
20 nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids  
25 whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 36% of the residues may be so changed.

30 The NOV34 protein of the invention includes the Olfactory Receptor-like protein whose sequence is provided in Table 34B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 34B while still encoding a protein that maintains its Olfactory Receptor-like activities and

physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 49% of the bases may be so changed.

The NOV34 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below and/or other pathologies. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from: developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders, Cell Shape disorders, Feeding disorders, control of feeding, potential obesity due to over-eating, potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm, adenocarcinoma, lymphoma, prostate cancer, uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease, multiple sclerosis, treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation, Dentatorubro-pallidoluysian atrophy (DRPLA), Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome and other diseases, disorders and conditions of the like.

NOV34 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV34 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV35

A disclosed NOV35 nucleic acid of 1102 nucleotides (also referred to as CG56718-01) encoding a novel Olfactory Receptor-like protein is shown in Table 35A. An open reading

frame was identified beginning with an ATG initiation codon at nucleotides 92-94 and ending with a TGA codon at nucleotides 1049-1051. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 35A, and the start and stop codons are in bold letters.

5

The NOV35 nucleic acid, located on chromosome 11, has 636 of 1006 bases (63%) identical to a gb:GENBANK-ID:AF133300|acc:AF133300.2 mRNA from *Mus musculus* (MOR 3'Beta1, MOR 3'Beta2, MOR 3'Beta3, and MOR 3'Beta4 genes, complete cds; Cbx3 pseudogene, complete sequence; and MOR 3'Beta5 and MOR 3'Beta6 genes, complete cds) ( $E = 1.2e^{-51}$ ).

10

A disclosed NOV35 polypeptide (SEQ ID NO:138) encoded by SEQ ID NO:137 is 319 amino acid residues and is presented using the one-letter code in Table 35B. Signal P, Psort and/or Hydropathy results predict that NOV35 contains a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000.

15

The disclosed NOV35 amino acid sequence has 160 of 309 amino acid residues (51%) identical to, and 219 of 309 amino acid residues (70%) similar to, the 321 amino acid residue ptrn:TREMBLNEW-ACC:AAG42364 protein from *Homo sapiens* (Human) (odorant receptor HOR3'BETA1) ( $E = 2.5e^{-81}$ ).

20

NOV35 is predicted to be expressed in at least Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus

callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus and thymus tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

NOV35 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 35C.

| Table 35C. BLAST results for NOV35          |                                                                                                          |                |                  |                  |        |

G-Protein Coupled Receptor (GPCRs) have been identified as an extremely large family of protein receptors in a number of species. At the phylogenetic level they can be classified into four major subfamilies. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors. They are likely to be involved in the recognition and transduction of various signals mediated by G-Proteins, hence their name G-Protein Coupled Receptors. The human GPCR genes are generally intron-less and belong to four gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large family of GPCRs in a number of species. As members of the GPCR family, these receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are

likely to underlie the recognition and G-protein-mediated transduction of odorant signals. Like GPCRs, the ORs they can be expressed in a variety of tissues where they are thought to be involved in recognition and transmission of a variety of signals. The human OR genes are typically intron-less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The NOV35 nucleic acid of the invention encoding a Olfactory Receptor-like protein includes the nucleic acid whose sequence is provided in Table 35A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 35A while still encoding a protein that maintains its Olfactory Receptor-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 37% of the residues may be so changed.

The NOV35 protein of the invention includes the Olfactory Receptor-like protein whose sequence is provided in Table 35B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 35B while still encoding a protein that maintains its Olfactory Receptor-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 52% of the bases may be so changed.

The NOV35 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below and/or other pathologies. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from: developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders, Cell Shape disorders, Feeding disorders, control of feeding, potential obesity due to over-eating, potential disorders due to

starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm, adenocarcinoma, lymphoma, prostate cancer, uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease, multiple sclerosis, treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation, Dentatorubro-pallidoluysian atrophy (DRPLA), Hypophosphatemic rickets, autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome and other diseases, disorders and conditions of the like.

NOV35 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV35 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

## NOV36

NOV36 includes two novel cadherin 11-like proteins disclosed below. The disclosed sequences have been named NOV36a and NOV36b.

### NOV36a

A disclosed NOV36a nucleic acid of 2476 nucleotides (also referred to as CG56729-01) encoding a novel cadherin 11-like protein is shown in Table 36A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 46-48 and ending with a TGA codon at nucleotides 2389-2391. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 36A, and the start and stop codons are in bold letters.

The disclosed NOV36a nucleic acid sequence, located on chromosome 14, has 992 of 1514 bases (65%) identical to a gb:GENBANK-ID:HUMCA11A|acc:L34056.1 mRNA from *Homo sapiens* (cadherin-11 mRNA, complete cds) ( $E = 7.3e^{-145}$ ).

- 5 A disclosed NOV36a polypeptide (SEQ ID NO:140) encoded by SEQ ID NO:139 is 781 amino acid residues and is presented using the one-letter amino acid code in Table 36B. Signal P, Psort and/or Hydropathy results predict that NOV36a contains a signal peptide and is likely to be localized in the mitochondrial inner membrane with a certainty of 0.8227 in one embodiment and to the plasma membrane with a certainty of 0.4400 in an additional
- 10 embodiment. The most likely cleavage site for a NOV36a polypeptide is between amino acids 16 and 17: GWG-CM.

**Table 36B. Encoded NOV36a protein sequence (SEQ ID NO:140).**

The disclosed NOV36a amino acid sequence has 434 of 746 amino acid residues (58%) identical to, and 552 of 746 amino acid residues (73%) similar to, the 796 amino acid residue ptnr:SWISSPROT-ACC:P55287 protein from *Homo sapiens* (Human) (CADHERIN-11 precursor (osteoblast-cadherin) (OB-cadherin) (OSF-4)) ( $E = 2.3e^{-229}$ ).

NOV36a is predicted to be expressed in at least Cerebral Medulla/Cerebral white matter, Gall Bladder, Retina, Temporal Lobe and Uterus. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, NOV36a is predicted to be expressed in the following tissues because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:HUMCA11A|acc:L34056.1) a closely related *Homo sapiens* cadherin-11 mRNA, complete cds homolog in species *Homo sapiens*: osteoblasts.

### NOV36b

A disclosed NOV36b nucleic acid of 2476 nucleotides (also referred to as CG56729-02) encoding a novel Cadherin 11-like protein is shown in Table 36C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 46-48 and ending with a TGA codon at nucleotides 2389-2391. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 36C, and the start and stop codons are in bold letters.

```

The disclosed NOV36b nucleic acid sequence, located on chromosome 11, has 1100 of 1109 bases (99%) identical to a gb:GENBANK-ID:AK025342|acc:AK025342.1 mRNA from *Homo sapiens* (cDNA: FLJ21689 fis, clone COL09459) ( $E = 2.3e^{-240}$ ).

- 5 A disclosed NOV36b polypeptide (SEQ ID NO:142) encoded by SEQ ID NO:141 is 781 amino acid residues and is presented using the one-letter amino acid code in Table 36D. Signal P, Psort and/or Hydropathy results predict that NOV36b contains a signal peptide and is likely to be localized to the mitochondrial inner membrane with a certainty of 0.8227 in one embodiment and to the plasma membrane with a certainty of 0.4400 in an additional
- 10 embodiment. The most likely cleavage site for a NOV36b peptide is between amino acids 16 and 17: GWG-CM.

**Table 36D. Encoded NOV36b protein sequence (SEQ ID NO:142).**

- The disclosed NOV36b amino acid sequence has 435 of 746 amino acid residues (58%) identical to, and 553 of 746 amino acid residues (74%) similar to, the 796 amino acid residue ptrn:SWISSNEW-ACC:P55287 protein from *Homo sapiens* (Human) (cadherin-11 precursor (osteoblast-cadherin) (OB-cadherin) (OSF-4)) ( $E = 2.5e^{-230}$ ).
- 15

NOV36b is predicted to be expressed in at least the following tissues: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia

nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea and uterus. Expression information was derived from the tissue sources of the

5 sequences that were included in the derivation of the NOV36b sequence.

In addition, NOV36b is predicted to be expressed in the following tissues because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:AK025342|acc:AK025342.1) a closely related *Homo sapiens* cDNA: FLJ21689 fis, clone COL09459 homolog in species *Homo sapiens*: osteoblasts.

10 NOV36a also has homology to the amino acid sequences shown in the BLASTP data listed in Table 36E.

**Table 36E. BLAST results for NOV36a**

Tables 36G-P list the domain description from DOMAIN analysis results against NOV36. This indicates that the NOV36 sequence has properties similar to those of other proteins known to contain this domain.

**Table 36G. Domain Analysis of NOV36**

gnl|Pfam|pfam01049, Cadherin\_C\_term, Cadherin cytoplasmic region.  
Cadherins are vital in cell-cell adhesion during tissue differentiation. Cadherins are linked to the cytoskeleton by catenins. Catenins bind to the cytoplasmic tail of the cadherin. Cadherins cluster to form foci of homophilic binding units. A key determinant to the strength of the binding that it is mediated by cadherins is the juxtamembrane region of the cadherin. This region induces clustering and also binds to the protein p120ctn. (SEQ ID NO:827)

- 5 Cadherins, first discovered in mouse teratocarcinoma cells, are a family of animal glycoproteins responsible for calcium-dependent cell-cell adhesion. Cadherins preferentially interact with themselves in a homophilic manner in connecting cells; thus acting as both receptor and ligand. There are a number of different isoforms distributed in a tissue-specific manner in a wide variety of organisms. Cells containing different cadherins tend to segregate
- 10 in vitro, while those that contain the same cadherins tend to preferentially aggregate together. This observation is linked to the finding that cadherin expression causes morphological changes involving the positional segregation of cells into layers, suggesting they may play an important role in the sorting of different cell types during morphogenesis, histogenesis and regeneration. They may also be involved in the regulation of tight and gap junctions, and in
- 15 the control of intercellular spacing. Cadherins are evolutionary related to the desmogleins which are component of intercellular desmosome junctions involved in the interaction of plaque proteins. The first three cadherins to be described were *E-cadherin* is present on many types of epithelial cells; *N-cadherin* on nerve, muscle, and lens cells; and *P-cadherin* on cells in the placenta and epidermis.
- 20 The NOV36 proteins bear close resemblance to cadherin-11, a member of the cadherin family of proteins, expressed in osteoblasts. The tissue expression in brain, uterus and retina of these NOV36 proteins indicate they might play an important role during organogenesis and development.
- 25 The disclosed NOV36 nucleic acid of the invention encoding a cadherin 11-like protein includes the nucleic acid whose sequence is provided in Table 36A, 36C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 36A or 36C while still encoding a protein that maintains its cadherin 11-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are
- 30 complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or
- 35 derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense

binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, in one embodiment up to about 35% of the NOV36a residues may be so changed and in an additional embodiment up to about 1% of the NOV36b residues may be so changed.

5           The disclosed NOV36 protein of the invention includes the cadherin 11-like protein whose sequence is provided in Table 36B or 36D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 36B or 36D while still encoding a protein that maintains its cadherin 11-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein,  
10           up to about 43% of the NOV36a and NOV36b bases may be so changed.

          The above defined information for this invention suggests that these cadherin 11-like proteins (NOV36) is a member of a "cadherin 11 family". Therefore, the NOV36 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential  
15           therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

20           The nucleic acids and proteins of NOV36 are useful in Von Hippel-Lindau (VHL) syndrome, cirrhosis, transplantation, endometriosis, fertility, anemia, ataxia-telangiectasia, autoimmune disease, hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, allergies, immunodeficiencies, graft versus host disease (GVHD), lymphoedema, muscular dystrophy, Lesch-Nyhan syndrome, myasthenia gravis, and/or other pathologies and disorders.

25           NOV36 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV36 protein have multiple  
30           hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

## NOV37

A disclosed NOV37 nucleic acid of 8575 nucleotides (also referred to as CG56733-01) encoding a novel Ten-M2-like protein is shown in Table 37A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 199-201 and ending with a TAA codon at nucleotides 8476-8478. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 37A, and the start and stop codons are in bold letters.

The NOV37 nucleic acid, located on chromosome 5, has 4965 of 5004 bases (99%) identical to a gb:GENBANK-ID:AB032953|acc:AB032953.1 mRNA from *Homo sapiens* (mRNA for KIAA1127 protein, partial cds) (E = 0.0).

A disclosed NOV37 polypeptide (SEQ ID NO:144) encoded by SEQ ID NO:143 is 2759 amino acid residues and is presented using the one-letter code in Table 37B. Signal P, Psort and/or Hydropathy results predict that NOV37 does not contain a signal peptide and is likely to be localized extracellularly with a certainty of 0.7900 in one embodiment, to the plasma membrane with a certainty of 0.7900 in another embodiment and to the nucleus with a certainty of 0.6000 in an additional embodiment.

**Table 37B. Encoded NOV37 protein sequence (SEQ ID NO:144)**

10

The disclosed NOV37 amino acid sequence has 2634 of 2764 amino acid residues (95%) identical to, and 2679 of 2764 amino acid residues (96%) similar to, the 2764 amino acid residue ptnr:SPTREMBL-ACC:Q9WTS5 protein from *Mus musculus* (Mouse) (TEN-M2) (E = 0.0).

NOV37 is predicted to be expressed in at least Amygdala, Brain, Bronchus, Cerebral Medulla/Cerebral white matter, Cochlea, Coronary Artery, Epidermis, Hair Follicles, Hippocampus, Hypothalamus, Kidney, Left cerebellum, Lung, Lymph node, Parietal Lobe, Pineal Gland, Retina, Right Cerebellum, Substantia Nigra, Vulva and Whole Organism. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, NOV37 is predicted to be expressed in the following tissues because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:AB032953|acc: AB032953.1) a closely related *Homo sapiens* mRNA for KIAA1127 protein, partial cds homolog in species *Homo sapiens*: Amygdala, Brain, Bronchus, Cerebral Medulla/Cerebral white matter, Cochlea, Coronary Artery, Epidermis, Hair Follicles, Hippocampus, Hypothalamus, Kidney, Left cerebellum, Lung, Lymph node, Parietal Lobe, Pineal Gland, Retina, Right Cerebellum and Substantia Nigra.

NOV37 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 37C.

| Table 37C. BLAST results for NOV37                    |                                                                                                        |                |                     |                    |        |

Neurestin shows homology to a neuregulin gene product, human gamma-heregulin, a *Drosophila* receptor-type pair-rule gene product, Odd Oz (Odz) / Ten(m), and Ten(a), suggesting a possible function in synapse formation and morphogenesis. A mouse neurestin homolog has independently been cloned as DOC4 from the NIH-3T3 cell line. Northern blot analysis showed that neurestin is highly expressed in the brain and also in other tissues at much lower levels. In situ hybridization studies showed that neurestin is expressed in many types of neurons, including pyramidal cells in the cerebral cortex and tufted cells in the olfactory bulb during development. In adults, neurestin is mainly expressed in olfactory and hippocampal granule cells, which are known to be generated throughout adulthood. Nonetheless, in adults the expression of neurestin was experimentally induced in external tufted cells during regeneration of olfactory sensory neurons. These results suggest a role for neurestin in neuronal development and regeneration in the central nervous system

Neurestin is a putative transmembrane protein whose expression is developmentally regulated in neurons. Neurestin expression pattern were examined in mitral/tufted cells in the developing rat olfactory bulb. In the main olfactory bulb, neurestin expression was segregated in the dorso-rostral area and in the ventro-caudal area, but not in between. In the accessory  
5 olfactory bulb, neurestin expression was found only in the far caudal area. This area did not completely correspond to a caudal half of the vomeronasal nerve and glomerular layers positive for a G-protein Go alpha. These spatio-temporal expression patterns suggest that neurestin functions as a target recognition molecule that specifies zonal projection patterns of olfactory and vomeronasal sensory neurons

10 The NOV37 nucleic acid of the invention encoding a Ten-M2-like protein includes the nucleic acid whose sequence is provided in Table 37A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 37A while still encoding a protein that maintains its Ten-M2-like activities and physiological functions, or a fragment of such a nucleic acid. The  
15 invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar  
20 phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 1% of the residues may be so changed.

25 The NOV37 protein of the invention includes the Ten-M2-like protein whose sequence is provided in Table 37B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 37B while still encoding a protein that maintains its Ten-M2-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 35% of the bases  
30 may be so changed.

The NOV37 nucleic acids and proteins of the invention are useful in potential diagnostic and therapeutic applications implicated in various diseases and disorders described below and/or other pathologies. For example, the compositions of the present invention will have efficacy for treatment of patients suffering from: brain disorders including epilepsy,

eating disorders, schizophrenia, ADD, cancer, heart disease, inflammation and autoimmune disorders including Crohn's disease, IBD, allergies, rheumatoid and osteoarthritis, inflammatory skin disorders, allergies, blood disorders, psoriasis, colon cancer, leukemia, AIDS, thalamus disorders, metabolic disorders including diabetes and obesity, lung diseases  
 5 such as asthma, emphysema, cystic fibrosis, and cancer, pancreatic disorders including pancreatic insufficiency and cancer, and prostate disorders including prostate cancer and other diseases, disorders and conditions of the like.

NOV37 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in  
 10 therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV37 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human  
 15 disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV38

A disclosed NOV38 nucleic acid of 1090 nucleotides (also referred to as CG56737-01) encoding a novel Activin Beta C Chain-like protein is shown in Table 38A. An open reading  
 20 frame was identified beginning with an ATG initiation codon at nucleotides 3-5 and ending with a TAG codon at nucleotides 1068-1070. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 38A, and the start and stop codons are in bold letters.

The disclosed NOV38 nucleic acid sequence, located on chromosome 12q13.1, has 748 of 935 bases (80%) identical to a gb:GENBANK-ID:MMU96386|acc:U96386.1 mRNA from *Mus musculus* (activin beta E subunit mRNA, complete cds) ( $E = 5.2e^{-120}$ ).

A disclosed NOV38 polypeptide (SEQ ID NO:146) encoded by SEQ ID NO:145 is 355 amino acid residues and is presented using the one-letter amino acid code in Table 38B. Signal P, Psort and/or Hydropathy results predict that NOV38 contains a signal peptide and is likely to be localized extracellularly with a certainty of 0.5135. The most likely cleavage site for a NOV38 peptide is between amino acids 18 and 19: TVA-TP.

The disclosed NOV38 amino acid sequence has 217 of 355 amino acid residues (61%) identical to, and 253 of 355 amino acid residues (71%) similar to, the 352 amino acid residue ptnr:SWISSPROT-ACC:P55103 protein from *Homo sapiens* (Human) (inhibin beta C chain precursor (activin beta-C chain)) ( $E = 7.6e^{-103}$ ).

NOV38 is predicted to be expressed in at least ovary and liver. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

Possible small nucleotide polymorphisms (SNPs) found for NOV38 are listed in Table

38C.

Activins are homo- or heterodimers of related beta subunits (see 147290) while inhibins are dimers composed of an alpha subunit (147380) and an activin beta subunit (summarized in Schmitt et al., Genomics 1996, 32(3):358-66). Activin proteins belong to the TGF-beta superfamily (see 190180), the members of which have important roles in cell  
5 determination, differentiation, and growth.

TGFB is a multifunctional peptide that controls proliferation, differentiation, and other functions in many cell types. It was first identified by its ability to cause phenotypic transformation of rat fibroblasts. TGFB is chemically distinct from TGFA. It has essentially no sequence homology with TGFA or with epidermal growth factor, of which TGFA is an  
10 analog. Members of the same gene family as TGFB include inhibin, which inhibits pituitary secretion of follicle stimulating hormone, and Mullerian inhibitory substance, which is produced by the testis and is responsible for regression of the Mullerian ducts (anlagen of the female reproductive system) in the male embryo. Many cells synthesize TGFB and almost all of them have specific receptors for this peptide. Alpha and beta TGFs are classes of  
15 transforming growth factors. TGFB acts synergistically with TGFA in inducing transformation. It also acts as a negative autocrine growth factor.

TGF-beta plays an important role in wound healing. A number of pathologic conditions, such as idiopathic pulmonary fibrosis, scleroderma, and keloids, which share the characteristic of fibrosis, are associated with increased TGF-beta-1 expression.

20 The disclosed NOV38 nucleic acid of the invention encoding a Activin Beta C Chain-like protein includes the nucleic acid whose sequence is provided in Table 38A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 38A while still encoding a protein that maintains its Activin Beta C Chain-like activities and physiological functions, or a  
25 fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example,  
30 modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic

acids, and their complements, in one embodiment up to about 20% of the NOV38 residues may be so changed.

The disclosed NOV38 protein of the invention includes the Activin Beta C Chain-like protein whose sequence is provided in Table 38B. The invention also includes a mutant or  
5 variant protein any of whose residues may be changed from the corresponding residue shown in Table 38B while still encoding a protein that maintains its Activin Beta C Chain-like activities and physiological functions, or a functional fragment thereof. In one embodiment a mutant or variant protein of NOV38, up to about 39% of the bases may be so changed.

The above defined information for this invention suggests that these Activin Beta C  
10 Chain-like proteins (NOV38) is a member of a "Activin Beta C Chain family". Therefore, the NOV38 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug  
15 targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The nucleic acids and proteins of NOV38 are useful in Alzheimer disease-5, Myxoid liposarcoma, Stickler syndrome, type I (3), SED, Alpha-ketoglutarate dehydrogenase  
20 deficiency, Cerebral cavernous malformations-2, Greig cephalopolysyndactyly syndrome, Hyperinsulinism, familial, MODY, type 2, Pallister-Hall syndrome, Polydactyly, postaxial, types A1 and B, Polydactyly, postaxial, type IV, Retinitis pigmentosa-9, Charcot-Marie-Tooth neuropathy-2D, Colton blood group, Deafness, autosomal dominant 5, Macular dystrophy, dominant cystoid, Radioulnar synostosis with amegakaryocytic thrombocytopenia, Von  
25 Hippel-Lindau (VHL) syndrome, cirrhosis, transplantation, fertility and/or other pathologies and disorders.

NOV38 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods  
30 known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV38 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human

disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV39

NOV39 includes novel Activin Beta C Chain-like and Inhibin Beta E Chain Precursor-like proteins disclosed below. The disclosed sequences have been named NOV39a and NOV39b.

### NOV39a

A disclosed NOV39a nucleic acid of 1112 nucleotides (also referred to as CG56737-02) encoding a novel Inhibin Beta E Chain Precursor-like protein is shown in Table 39A. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 40-42 and ending with a TAG codon at nucleotides 1090-1092. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 39A, and the start and stop codons are in bold letters.

The disclosed NOV39a nucleic acid sequence, located on chromosome 7p13-15, has 923 of 1110 bases (83%) identical to a gb:GENBANK-ID:MMU96386|acc:U96386.1 mRNA from *Mus musculus* (activin beta E subunit mRNA, complete cds) ( $E = 2.1e^{-165}$ ).

A disclosed NOV39a polypeptide (SEQ ID NO:148) encoded by SEQ ID NO:147 is 350 amino acid residues and is presented using the one-letter amino acid code in Table 39B. Signal P, Psort and/or Hydropathy results predict that NOV39a contains no signal peptide and is likely to be localized extracellularly with a certainty of 0.3700. The most likely cleavage site for a NOV39a peptide is between amino acids 19 and 20: VRA-QG.

**Table 39B. Encoded NOV39a protein sequence (SEQ ID NO:148).**

The disclosed NOV39a amino acid sequence has 287 of 350 amino acid residues (82%) identical to, and 301 of 350 amino acid residues (86%) similar to, the 350 amino acid residue ptnr:SWISSPROT-ACC:O08717 protein from *Mus musculus* (Mouse) (Inhibin Beta E Chain Precursor (Activin Beta-E Chain)) ( $E = 5.0e^{-154}$ ).

NOV39a is predicted to be expressed in at least the following tissues: ovary and liver. Expression information was derived from the tissue sources of the sequences that were included in the derivation of the NOV39a sequence.

**NOV39b**

A disclosed NOV39b nucleic acid of 1112 nucleotides (also referred to as CG56647-03) encoding a novel Inhibin Beta E Chain-like protein is shown in Table 39C. An open reading frame was identified beginning with an ATG initiation codon at nucleotides 40-42 and ending with a TAG codon at nucleotides 1090-1092. Putative untranslated regions, if any, found upstream from the initiation codon and downstream from the termination codon are underlined in Table 39C, and the start and stop codons are in bold letters.

The disclosed NOV39b nucleic acid sequence, located on chromosome 7p13-15, has 920 of 1110 bases (82%) identical to a gb:GENBANK-ID:MMU96386|acc:U96386.1 mRNA from *Mus musculus* (activin beta E subunit mRNA, complete cds) ( $E = 3.7e^{-164}$ ).

- A disclosed NOV39b polypeptide (SEQ ID NO:150) encoded by SEQ ID NO:149 is 350 amino acid residues and is presented using the one-letter amino acid code in Table 39D. Signal P, Psort and/or Hydropathy results predict that NOV39b contains a signal peptide and is likely to be localized extracellularly with a certainty of 0.3700. The most likely cleavage site for a NOV39b peptide is between amino acids 19 and 20: VRA-QG.

**Table 39D. Encoded NOV39b protein sequence (SEQ ID NO:150).**

- The disclosed NOV39b amino acid sequence has 285 of 350 amino acid residues (81%) identical to, and 299 of 350 amino acid residues (85%) similar to, the 350 amino acid residue ptnr:SWISSPROT-ACC:O08717 protein from *Mus musculus* (Mouse) (Inhibin Beta E Chain Precursor (Activin Beta-E Chain)) ( $E = 1.5e^{-152}$ ).

NOV39b is predicted to be expressed in at least the following tissues: ovary and liver. Expression information was derived from the tissue sources of the sequences that were included in the derivation of the NOV39b sequence.

- Possible small nucleotide polymorphisms (SNPs) found for NOV39a are listed in Table 39E.

| Table 39E: SNPs    |       |             |     |
|--------------------|-------|-------------|-----|
| Consensus Position | Depth | Base Change | PAF |
| 1095               | 11    | T > C       | N/A |

Possible small nucleotide polymorphisms (SNPs) found for NOV39b are listed in Table 39F.

| Table 39F: SNPs    |       |             |       |
|--------------------|-------|-------------|-------|
| Consensus Position | Depth | Base Change | PAF   |
| 933                | 9     | C > T       | 0.222 |

- NOV39a also has homology to the amino acid sequences shown in the BLASTP data listed in Table 39G.

| Table 39G. BLAST results for NOV39a |                   |                |                 |                  |        |

Activins are homo- or heterodimers of related beta subunits (see 147290) while  
 10 inhibins are dimers composed of an alpha subunit (147380) and an activin beta subunit  
 (summarized in Schmitt et al., Genomics 1996, 32(3):358-66). Activin proteins belong to the  
 TGF-beta superfamily (see 190180), the members of which have important roles in cell  
 determination, differentiation, and growth.

TGFB is a multifunctional peptide that controls proliferation, differentiation, and other  
 15 functions in many cell types. It was first identified by its ability to cause phenotypic  
 transformation of rat fibroblasts. TGFB is chemically distinct from TGFA. It has essentially no  
 sequence homology with TGFA or with epidermal growth factor, of which TGFA is an  
 analog. Members of the same gene family as TGFB include inhibin, which inhibits pituitary  
 secretion of follicle stimulating hormone, and Mullerian inhibitory substance, which is  
 20 produced by the testis and is responsible for regression of the Mullerian ducts (anlagen of the  
 female reproductive system) in the male embryo. Many cells synthesize TGFB and almost all  
 of them have specific receptors for this peptide. Alpha and beta TGFs are classes of  
 transforming growth factors. TGFB acts synergistically with TGFA in inducing  
 transformation. It also acts as a negative autocrine growth factor.

25 TGF-beta plays an important role in wound healing. A number of pathologic  
 conditions, such as idiopathic pulmonary fibrosis, scleroderma, and keloids, which share the  
 characteristic of fibrosis, are associated with increased TGF-beta-1 expression.

The disclosed NOV39 nucleic acid of the invention encoding a Activin Beta C Chain-  
 like protein includes the nucleic acid whose sequence is provided in Table 39A, 39C or a  
 30 fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose  
 bases may be changed from the corresponding base shown in Table 39A, or 39C while still  
 encoding a protein that maintains its Activin Beta C Chain-like activities and physiological  
 functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids  
 whose sequences are complementary to those just described, including nucleic acid fragments  
 35 that are complementary to any of the nucleic acids just described. The invention additionally  
 includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures  
 include chemical modifications. Such modifications include, by way of non-limiting example,  
 modified bases, and nucleic acids whose sugar phosphate backbones are modified or

derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, in one embodiment up to about 17% of the NOV39a residues  
5 may be so changed, and in an additional embodiment up to about 18% of the NOV39b residues may be so changed.

The disclosed NOV39 protein of the invention includes the Activin Beta C Chain-like protein whose sequence is provided in Table 39B, or 39D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding  
10 residue shown in Table 39B, or 39D while still encoding a protein that maintains its Activin Beta C Chain-like activities and physiological functions, or a functional fragment thereof. In one embodiment a mutant or variant protein of NOV39a, up to about 39% of the bases may be so changed.

The above defined information for this invention suggests that these Activin Beta C  
15 Chain-like proteins (NOV39) is a member of a "Activin Beta C Chain family". Therefore, the NOV39 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug  
20 targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The nucleic acids and proteins of NOV39 are useful in Alzheimer disease-5, Myxoid liposarcoma, Stickler syndrome, type I (3), SED, Alpha-ketoglutarate dehydrogenase  
25 deficiency, Cerebral cavernous malformations-2, Greig cephalopolysyndactyly syndrome, Hyperinsulinism, familial, MODY, type 2, Pallister-Hall syndrome, Polydactyly, postaxial, types A1 and B, Polydactyly, postaxial, type IV, Retinitis pigmentosa-9, Charcot-Marie-Tooth neuropathy-2D, Colton blood group, Deafness, autosomal dominant 5, Macular dystrophy, dominant cystoid, Radioulnar synostosis with amegakaryocytic thrombocytopenia, Von  
30 Hippel-Lindau (VHL) syndrome, cirrhosis, transplantation, fertility and/or other pathologies and disorders.

NOV39 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immunospecifically to the novel substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods

known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. For example the disclosed NOV39 protein have multiple hydrophilic regions, each of which can be used as an immunogen. This novel protein also has value in development of powerful assay system for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV40

A disclosed NOV40 nucleic acid of 1606 nucleotides (also referred to as CG56097-01) encoding a UDP glycosyltransferase-like protein is shown in Table 40A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 1-3 and ending with a TAG codon at nucleotides 1600-1602. The start and stop codons are shown in bold in Table 40A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 40A. NOV40 nucleotide sequence (SEQ ID NO:151).**

In a search of public sequence databases, the NOV40 nucleic acid sequence, located on chromosome 4, has 1305 of 1606 bases (81%) identical to a gb:GENBANK-ID:HUMUDPGTA|acc:J05428.1 mRNA from *Homo sapiens* (Human 3,4-catechol estrogen UDP-glucuronosyltransferase mRNA, complete cds) ( $E = 6.4e^{-217}$ ).

The disclosed NOV40 polypeptide (SEQ ID NO:152) encoded by SEQ ID NO:151 has 533 amino acid residues and is presented in Table 40B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV40 has no signal peptide and is likely to be localized to the endoplasmic reticulum (membrane) with a certainty of 0.8200.

Alternatively, NOV40 may also localize to the plasma membrane with a certainty of 0.4600, to the microbody (peroxisome) with a certainty of 0.3012, or to the lysosome (membrane) with a certainty of 0.2000. The most likely cleavage site for NOV40 is between positions 20 and 21: SSS-GS.

A search of sequence databases reveals that the NOV40 amino acid sequence has 353 of 533 amino acid residues (66%) identical to, and 412 of 533 amino acid residues (77%) similar to, the 529 amino acid residue ptnr:SWISSPROT-ACC:P16662 protein from *Homo sapiens* (Human) (UDP-Glucuronosyltransferase 2b7 Precursor, Microsomal (EC 2.4.1.17) (UDPGT) (3,4-Catechol Estrogen Specific) (UDPGTH-2)) ( $E = 7.2e^{-185}$ ).

NOV40 is predicted to be expressed in at least the following tissues: liver tissue. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

NOV40 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 40C.

**Table 40C. BLAST results for NOV40**

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 40D. In the ClustalW alignment of the NOV40 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

The UDP-glucuronosyltransferases, a group of isoenzymes located primarily in hepatic endoplasmic reticulum and nuclear envelope, are encoded by a large multigene family that has evolved to produce catalysts with differing but overlapping substrate specificities. Two subfamilies are recognized by sequence identities. UGT1 consists of at least 4 isoenzymes that catalyze the glucuronidation of phenols and bilirubin. All 4 map to chromosome 2 and probably derive from the same gene (UGT1). The UGT2 family contains at least 5 members catalyzing steroid or bile acid glucuronidation. Members of the subfamily share 65 to 90% amino acid sequence identity. However, unlike the phenol UGT cDNAs, where the high degree of identity is concentrated in the 3-prime region of the cDNA, the steroid UGTs have a high degree of sequence homology throughout the cDNA. The disclosed NOV40 nucleic acid of the invention encoding a UDP Glycosyltransferase-like protein includes the nucleic acid whose sequence is provided in Table 40A or a fragment thereof. The invention also includes a

mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 40A while still encoding a protein that maintains its UDP[ Glycosyltransferase -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are  
5 complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or  
10 derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 19 percent of the bases may be so changed.

The disclosed NOV40 protein of the invention includes the UDP Glycosyltransferase -  
15 like protein whose sequence is provided in Table 40B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 40B while still encoding a protein that maintains its UDP Glycosyltransferase -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 35 percent of the residues may be so changed.

20 The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this UDP Glycosyltransferase -like protein (NOV40) is a member of a "UDP Glycosyltransferase family". Therefore, the NOV40 nucleic acids and proteins identified here may be useful in potential therapeutic applications  
25 implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues  
30 and cell types composing (but not limited to) those defined here.

The NOV40 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in brain disorders including Crigler-Najjar syndrome, Gilbert syndrome, and/or other diseases and pathologies.

NOV40 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV40 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the “Anti-  
 5 NOVX Antibodies” section below. The disclosed NOV40 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### 10 NOV41

NOV41 includes three novel adrenal secretory serine protease-like proteins disclosed below. The disclosed sequences have been named NOV41a and NOV41b.

#### NOV41a

A disclosed NOV41a nucleic acid of 2155 nucleotides (also referred to as CG56680-  
 15 01) encoding a Sodium/Hydrogen Exchanger 4-like protein is shown in Table 41A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 16-18 and ending with a TAG codon at nucleotides 2140-2142. The start and stop codons are shown in bold in Table 41A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 41A. NOV41a nucleotide sequence (SEQ ID NO:153).**

In a search of public sequence databases, the NOV41a nucleic acid sequence, located on chromosome 2, has 1820 of 2156 bases (84%) identical to a gb:GENBANK-ID:RATNHEXIV|acc:M85301.1 mRNA from *Rattus norvegicus* (Rat sodium-hydrogen exchange protein-isoform 4 (NHE-4) mRNA, complete cds) ( $E = 6.4e^{-217}$ ).

The disclosed NOV41a polypeptide (SEQ ID NO:154) encoded by SEQ ID NO:153 has 708 amino acid residues and is presented in Table 41B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV41a has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.8200. Alternatively, NOV41a may also localize to the Golgi body with a certainty of 0.4600, to the endoplasmic reticulum (membrane) with a certainty of 0.3700, or to the endoplasmic reticulum (lumen) with a certainty of 0.1000. The most likely cleavage site for NOV41a is between positions 26 and 27: SEA-SS.

**Table 41B. Encoded NOV41a protein sequence (SEQ ID NO:154).**

A search of sequence databases reveals that the NOV41a amino acid sequence has 599 of 688 amino acid residues (87%) identical to, and 631 of 688 amino acid residues (91%) similar to, the 717 amino acid residue ptrn:SWISSPROT-ACC:P26434 protein from *Rattus norvegicus* (Rat) (Sodium/Hydrogen Exchanger 4 (NA(+)/H(+)) Exchanger 4) (NHE-4)) ( $E = 0.0$ ).

NOV41a is predicted to be expressed in at least the stomach. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, the sequence is predicted to be expressed in stomach, colon and small intestine; lesser amounts in kidney, brain, uterus and skeletal muscle because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:RATNHEXIV|acc:M85301.1) a closely related Rat sodium-hydrogen exchange protein-isoform 4 (NHE-4) mRNA, complete cds homolog.

#### 5        **NOV41b**

In the present invention, the target sequence identified previously, NOV41a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was  
 10 examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on in silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely  
 15 related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary  
 20 gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with  
 25 another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated NOV41b. This differs from the previously identified sequence (NOV41a) in having 17 different aminoacids.

A disclosed NOV41b nucleic acid of 2436 nucleotides (also referred to as CG56680-  
 30 02) encoding a Sodium/Hydrogen Exchanger 4-like protein is shown in Table 41C. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 86-88 and ending with a TAA codon at nucleotides 2369-2371. The start and stop codons are shown in bold in Table 41C, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV41b nucleic acid sequence, located  
 on chromosome 2, has 1818 of 2163 bases (84%) identical to a gb:GENBANK-  
 ID:RATNHEXIV|acc:M85301.1 mRNA from *Rattus norvegicus* (Rat sodium-hydrogen  
 5 exchange protein-isoform 4 (NHE-4) mRNA, complete cds) (E = 0.0).

The disclosed NOV41b polypeptide (SEQ ID NO:156) encoded by SEQ ID NO:155  
 has 761 amino acid residues and is presented in Table 41D using the one-letter amino acid  
 code. Signal P, Psort and/or Hydropathy results predict that NOV41b has no signal peptide  
 and is likely to be localized to the plasma membrane with a certainty of 0.8200. Alternatively,  
 10 NOV41b may also localize to the Golgi body with a certainty of 0.4600, to the endoplasmic  
 reticulum (membrane) with a certainty of 0.3700, or to the endoplasmic reticulum (lumen)  
 with a certainty of 0.1000. The most likely cleavage site for NOV41b is between positions 26  
 and 27: SEA-SS.

A search of sequence databases reveals that the NOV41b amino acid sequence has 606 of 717 amino acid residues (84%) identical to, and 641 of 717 amino acid residues (89%) similar to, the 717 amino acid residue ptnr:SWISSPROT-ACC:P26434 protein from Rattus norvegicus (Rat) (Sodium/Hydrogen Exchanger 4 (NA(+)/H(+) Exchanger 4) (NHE-4)) (E = 0.0).

NOV41b is predicted to be expressed in at least adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea and uterus. .

NOV41a also has homology to the amino acid sequences shown in the BLASTP data listed in Table 41E.

| Table 41E. BLAST results for NOV41a             |                                                                                                        |                |                  |                  |        |

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 41F. In the ClustalW alignment of the NOV41 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Na<sup>+</sup>/H<sup>+</sup> antiporters are key transporters in maintaining the pH of actively metabolizing cells. Na<sup>+</sup>/H<sup>+</sup> exchange proteins eject protons from cells, effectively eliminating excess acid from actively metabolising cells. Na<sup>+</sup>/H<sup>+</sup> exchange activity is also crucial for the regulation of cell volume, and for the reabsorption of NaCl across renal, intestinal, and other epithelia. These antiports exchange Na<sup>+</sup> for H<sup>+</sup> in an electroneutral manner, and this activity is carried out by a family of Na<sup>+</sup>/H<sup>+</sup> exchangers, or NHEs. In mammalian cells, Na<sup>+</sup>/H<sup>+</sup> exchange activity is found in both the plasma membrane and inner mitochondrial membrane. To date, six mammalian isoforms have been identified (designated NHE1-NHE6). These exchangers are highly-regulated (glyco)phosphoproteins, which, based on their primary structure, appear to contain 10-12 transmembrane regions at the N-terminus and a large cytoplasmic region at the C-terminus. The transmembrane regions M3-M12 share identity with other members of the

family. The M6 and M7 regions are highly conserved. Thus, this is thought to be the region that is involved in the transport of sodium and hydrogen ions. The cytoplasmic region has little similarity throughout the family. There is some evidence that they may exist in the cell membrane as homodimers, but the molecular mechanisms of antiport are unclear. Na<sup>+</sup>/H<sup>+</sup> antiporters play an important role in signal transduction.

The disclosed NOV41 nucleic acid of the invention encoding a Sodium/Hydrogen Exchanger 4 -like protein includes the nucleic acid whose sequence is provided in Table 41A, 41C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 41A or 41C while still encoding a protein that maintains its UDP[ Glycosyltransferase -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 16 percent of the bases may be so changed.

The disclosed NOV41 protein of the invention includes the Sodium/Hydrogen Exchanger 4 -like protein whose sequence is provided in Table 41B or 41D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 41B or 41D while still encoding a protein that maintains its Sodium/Hydrogen Exchanger 4 -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 37 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Sodium/Hydrogen Exchanger 4 -like protein (NOV41) is a member of a "Sodium/Hydrogen Exchanger 4 family". Therefore, the NOV41 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated

below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV41 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in brain disorders including hypercalcaemia, ulcers, inflammatory bowel disease, diverticular disease; diseases of the kidney including diabetes, autoimmune disease, renal artery stenosis, interstitial nephritis, and others; diseases of the brain including Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, epilepsy, and others; endometriosis, fertility, muscular dystrophy, Lesch-Nyhan syndrome, myasthenia gravis, and/or other diseases and pathologies.

NOV41 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV41 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV41 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV42

NOV42 includes three novel Kupffer Cell Receptor -like proteins disclosed below. The disclosed sequences have been named NOV42a, NOV42b, NOV42c, and NOV42d.

#### NOV42a

A disclosed NOV42a nucleic acid of 1760 nucleotides (also referred to as CG56682-01) encoding a Kupffer Cell Receptor -like protein is shown in Table 42A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 16-18 and ending with a TGA codon at nucleotides 1661-1663. The start and stop codons are shown in bold in Table 42A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 42A. NOV42a nucleotide sequence (SEQ ID NO:157).**

In a search of public sequence databases, the NOV42a nucleic acid sequence, located on chromosome 2, has 1214 of 1730 bases (70%) identical to a gb:GENBANK-ID:D88577|acc:D88577.1 mRNA from *Mus musculus* (mRNA for Kupffer cell receptor, complete cds) ( $E = 3.9e^{-162}$ ).

The disclosed NOV42a polypeptide (SEQ ID NO:158) encoded by SEQ ID NO:157 has 546 amino acid residues and is presented in Table 42B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV42a has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.7900. Alternatively, NOV42a may also localize to the microbody (peroxisome) with a certainty of 0.3000, to the Golgi body with a certainty of 0.3000, or to the endoplasmic reticulum (membrane) with a certainty of 0.2000. The most likely cleavage site for NOV42a is between positions 65 and 66: VVG-KP.

**Table 42B. Encoded NOV42A protein sequence (SEQ ID NO:158).**

A search of sequence databases reveals that the NOV42a amino acid sequence has 301 of 546 amino acid residues (55%) identical to, and 396 of 546 amino acid residues (72%) similar to, the 548 amino acid residue ptr:SWISSPROT-ACC:P70194 protein from *Mus musculus* (Mouse) (Kupffer Cell Receptor) ( $E = 0.0$ ).

5 NOV42a is predicted to be expressed in at least cartilage. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, the sequence is predicted to be expressed in :Kupffer cells (liver) because  
10 of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:D88577|acc:D88577.1) a closely related *Mus musculus* mRNA for Kupffer cell receptor, complete cds homolog.

#### NOV42b

In the present invention, the target sequence identified previously, NOV42a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by  
15 starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on in  
20 silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra,  
25 brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with  
30 other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide

the sequence reported below, which is designated NOV42b. This differs from the previously identified sequence (NOV42a) in having 3 less aminoacids and 26 different ones.

A disclosed NOV42b nucleic acid of 1769 nucleotides (also referred to as CG56682-02) encoding a Kupffer cell receptor-like protein is shown in Table 42C. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 23-25 and ending with a TGA codon at nucleotides 1670-1672. The start and stop codons are shown in bold in Table 42C, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV42b nucleic acid sequence, located on chromosome 2, has 1054 of 1469 bases (71%) identical to a gb:GENBANK-ID:D88577|acc:D88577.1 mRNA from *Mus musculus* (mRNA for Kupffer cell receptor, complete cds) ( $E = 1.1e^{-161}$ ).

The disclosed NOV42b polypeptide (SEQ ID NO:160) encoded by SEQ ID NO:159 has 549 amino acid residues and is presented in Table 42D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV42b has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.7900. Alternatively, NOV42b may also localize to the microbody (peroxisome) with a certainty of 0.3000, to the Golgi body with a certainty of 0.3000, or to the endoplasmic reticulum (membrane) with a certainty of 0.2000. The most likely cleavage site for NOV42b is between positions 67 and 68: VQQ-QT.

A search of sequence databases reveals that the NOV42b amino acid sequence has 304  
 of 549 amino acid residues (55%) identical to, and 401 of 549 amino acid residues (73%)  
 5 similar to, the 548 amino acid residue ptnr:SWISSPROT-ACC:P70194 protein from *Mus*  
*musculus* (Mouse) (Kupffer Cell Receptor) ( $E = 3.7e^{-158}$ ).

NOV42b is predicted to be expressed in at least adrenal gland, bone marrow, brain -  
 amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus,  
 brain - whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji,  
 10 mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle,  
 small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea and uterus.

**NOV42c**

A disclosed NOV42c nucleic acid of 1874 nucleotides (also referred to as CG56682-  
 03) encoding a Kupffer cell receptor-like protein is shown in Table 42E. An open reading  
 15 frame was identified beginning with a ATG initiation codon at nucleotides 1-3 and ending  
 with a TAA codon at nucleotides 1702-1704. The start and stop codons are shown in bold in  
 Table 42E, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV42c nucleic acid sequence, located on chromosome 2, has 689 of 993 bases (69%) identical to a gb:GENBANK-ID:D88577|acc:D88577.1 mRNA from *Mus musculus* (mRNA for Kupffer cell receptor, complete cds) ( $E = 1.6e^{-120}$ ).

The disclosed NOV42c polypeptide (SEQ ID NO:162) encoded by SEQ ID NO:161 has 567 amino acid residues and is presented in Table 42F using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV42c has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.7900. Alternatively, NOV42c may also localize to the microbody (peroxisome) with a certainty of 0.3000, to the Golgi body with a certainty of 0.3000, or to the endoplasmic reticulum (membrane) with a certainty of 0.2000. The most likely cleavage site for NOV42c is between positions 62 and 63: VQQ-QT.

**Table 42F Encoded NOV42c protein sequence (SEQ ID NO:162).**

A search of sequence databases reveals that the NOV42c amino acid sequence has 191 of 412 amino acid residues (46%) identical to, and 273 of 412 amino acid residues (66%) similar to, the 548 amino acid residue ptnr:SWISSNEW-ACC:P70194 protein from *Mus musculus* (Mouse) (Kupffer Cell Receptor) ( $E = 5.3e^{-92}$ ).

NOV42c is predicted to be expressed in at least the following tissues: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea and uterus. .

25

**NOV42d**

A disclosed NOV42d nucleic acid of 1985 nucleotides (also referred to as CG56682-04) encoding a Kupffer cell receptor-like protein is shown in Table 42G. An open reading frame was identified beginning with a GTC initiation codon at nucleotides 2-4 and ending with a TAA codon at nucleotides 1658-1660. The start and stop codons are shown in bold in Table 42G, and the 5' and 3' untranslated regions, if any, are underlined. Because the starting codon is not a traditional initiation codon, NOV42d could be a partial reading frame extending further into the 5'

In a search of public sequence databases, the NOV42d nucleic acid sequence, located on chromosome 2, has 705 of 1023 bases (68%) identical to a gb:GENBANK-ID:D88577|acc:D88577.1 mRNA from *Mus musculus* (mRNA for Kupffer cell receptor, complete cds) ( $E = 3.7e^{-124}$ ).

The disclosed NOV42d polypeptide (SEQ ID NO:164) encoded by SEQ ID NO:163 has 552 amino acid residues and is presented in Table 42H using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV42d has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.7900. Alternatively, NOV42d may also localize to the microbody (peroxisome) with a certainty of 0.3000, to the Golgi body with a certainty of 0.3000, or to the endoplasmic reticulum (membrane) with a

certainty of 0.2000. The most likely cleavage site for NOV42d is between positions 57 and 58: VQQ-QT.

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 42J. In the ClustalW alignment of the NOV42 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Kupffer cells are found in the linings of the liver sinusoids, and are phagocytic. A receptor uniquely found on the surface of rat Kupffer cells binds oligosaccharides terminating in galactose, N-acetylgalactosamine, and fucose. A number of different families of proteins share a conserved domain which was first characterized in some animal lectins. Animal lectins display a wide variety of architectures. They are classified according to the carbohydrate-recognition domain (CRD) of which there are two main types, S-type and C-type. C-type lectins (CTL) display a wide range of specificities and function as a calcium-dependent carbohydrate-recognition domain. They are found predominantly but not exclusively in vertebrates. CTLs can be classified into a number of subgroups based on their function and structure: 1) Collectins, represented by the soluble mannose-binding proteins of mammalian serum and liver; 2) Selectins, membrane-bound proteins involved in inflammation; and 3) Endocytic lectins, membrane-bound receptors that mediate endocytosis of glycoproteins. Endocytic lectins are type-II membrane proteins where the CTL domain is located at the C-terminal extremity of the proteins, and include the Kupffer Cell Receptor.

The disclosed NOV42 nucleic acid of the invention encoding a Kupffer Cell Receptor-like protein includes the nucleic acid whose sequence is provided in Table 42A, 42C, 42E, 42G, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any

of whose bases may be changed from the corresponding base shown in Table 42A, 42C, 42E, or 42G while still encoding a protein that maintains its Kupffer Cell Receptor -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including  
5 nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the  
10 chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 32 percent of the bases may be so changed.

The disclosed NOV42 protein of the invention includes the Kupffer Cell Receptor -  
15 like protein whose sequence is provided in Table 42B, 42D, 42F, or 42H. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 42B, 42D, 42F, or 42H while still encoding a protein that maintains its Kupffer Cell Receptor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 66 percent of the  
20 residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Kupffer Cell Receptor -like protein (NOV42) is a member of a "Kupffer Cell Receptor family". Therefore, the NOV42 nucleic  
25 acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene  
30 delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV42 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Von Hippel-Lindau (VHL) syndrome, cirrhosis, transplantation, arthritis, tendinitis, and/or other diseases and pathologies.

NOV42 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV42 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-  
 5 NOVX Antibodies" section below. The disclosed NOV42 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV43

A disclosed NOV43 nucleic acid of 1108 nucleotides (also referred to as CG56690-01) encoding a P2Y Purinoceptor -like protein is shown in Table 43A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 12-14 and ending with a TAA codon at nucleotides 1095-1097. The start and stop codons are shown in bold in Table  
 15 43A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 43A. NOV43 nucleotide sequence (SEQ ID NO:165).**

In a search of public sequence databases, the NOV43 nucleic acid sequence, located on chromosome 2, has 585 of 924 bases (63%) identical to a gb:GENBANK-  
 ID:GDP2Y3|acc:X98283.1 mRNA from *Gallus gallus* (*G.domesticus* mRNA for G protein-  
 20 coupled P2 receptor) ( $E = 3.6e^{-45}$ ).

The disclosed NOV43 polypeptide (SEQ ID NO:166) encoded by SEQ ID NO:165 has 361 amino acid residues and is presented in Table 43B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV43 has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively,  
 25 NOV43 may also localize to the mitochondrial inner membrane with a certainty of 0.5862, to

the mitochondrial intermembrane space with a certainty of 0.4114, or to the Golgi body with a certainty of 0.4000. The most likely cleavage site for NOV43 is between positions 13 and 14: SRS-GS.

**Table 43B. Encoded NOV43 protein sequence (SEQ ID NO:166).**

A search of sequence databases reveals that the NOV43 amino acid sequence has 105 of 261 amino acid residues (40%) identical to, and 153 of 261 amino acid residues (58%) similar to, the 328 amino acid residue ptnr:SWISSNEW-ACC:Q98907 protein from *Gallus gallus* (Chicken) (P2Y Purinoceptor 3 (P2Y3) (Nucleoside Diphosphate Receptor)) (E = 0.0).

NOV43 is predicted to be expressed in brain because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:GDP2Y3|acc:X98283.1) a closely related *G.domesticus* mRNA for G protein-coupled P2 receptor homolog in species *Gallus gallus*..

NOV43 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 43C.

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 43D. In the ClustalW alignment of the NOV43 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

The P2Y Purinoreceptor belongs to the family of G-Protein Coupled Receptors. G-protein-coupled receptors (GPCRs) constitute a vast protein family that encompasses a wide range of functions (including various autocrine, paracrine and endocrine processes). They show considerable diversity at the sequence level, on the basis of which they can be separated into distinct groups. We use the term clan to describe the GPCRs, as they embrace a group of families for which there are indications of evolutionary relationship, but between which there is no statistically significant similarity in sequence [1]. The currently known clan members include the rhodopsin-like GPCRs, the secretin-like GPCRs, the cAMP receptors, the fungal mating pheromone receptors, and the metabotropic glutamate receptor family. The rhodopsin-like GPCRs themselves represent a widespread protein family that includes hormone, neurotransmitter and light receptors, all of which transduce extracellular signals through interaction with guanine nucleotide-binding (G) proteins. Although their activating ligands vary widely in structure and character, the amino acid sequences of the receptors are very similar and are believed to adopt a common structural framework comprising 7 transmembrane (TM) helices. See CMKRL2 (601805). Using degenerate PCR to find cDNAs encoding new G protein coupled-receptors in human B cells, Owman et al. (1996) identified a CMKRL1 cDNA which encodes a 352-amino acid polypeptide with a calculated mass of 43 kD. The nearest homologs of this novel sequence are the chemoattractant leukocyte receptors, such as the C5a anaphylatoxin receptor and the FMLP receptor. Northern blotting revealed transcripts of 5 kb and 7.5 kb in several tissues of the immune system including spleen, thymus, and lymph node. Owman et al. (1996) considered the high level of expression in

lymphoid tissues suggestive of the role of CMKRL1 in the regulation of the inflammatory system. The authors mapped the CMKRL1 gene to 14q11.2-q12 by fluorescence in situ hybridization. Akbar et al. (1996) used a chicken P2Y3 cDNA to screen a human erythroleukemia (HEL) cell cDNA library and cloned a purinoceptor cDNA, which they  
5 termed P2Y7. Sequencing revealed an open reading frame coding for a polypeptide of 352 amino acids having 7 putative transmembrane domains. The P2Y7 receptor has 23 to 30% identity to other P2Y receptors, but forms a unique branch within the P2Y family. Northern blot analysis showed that the P2Y7 gene produced a 1.6-kb transcript which is expressed at highest levels in human heart, human skeletal muscle, rat heart, and rat cardiomyocytes and at  
10 lower levels in human brain and human liver. Akbar et al. (1996) noted that its expression in HEL cells is below the threshold of detection by Northern blot. Binding and displacement assays in COS-7 cells showed that P2Y7 has a high affinity for ATP and much less for UTP and ADP. The rank order of affinities in the binding series was distinct from any known for the P2Y1-P2Y6 receptors. Like other P2Y receptors, P2YR is coupled to phospholipase C and  
15 not to adenylate cyclase. Akbar et al. (1996) speculated that P2Y7 may be the cardiac P2Y receptor involved in the regulation of cardiac muscle contraction through modulation of L-type calcium currents. Akbar et al. (1996) used PCR on a panel of mouse-rodent somatic cell hybrids to localize the P2RY7 gene to human chromosome 14. Somers et al. (1997) did sequence tagged site (STS) mapping of the P2RY7 gene using the National Center for  
20 Biotechnology Information (NCBI) database. In this way, they positioned the P2RY7 gene between D14S283 and D14S264. Leukotriene B4 (LTB4) is a potent chemoattractant that is primarily involved in inflammation, immune responses, and host defense against infection (Samuelsson et al., 1987; Chen et al., 1994). LTB4 activates inflammatory cells by binding to its cell surface receptor, BLTR. LTB4 can also bind and activate the intranuclear transcription  
25 factor PPAR-alpha, resulting in the activation of genes that terminate inflammatory processes (Devchand et al., 1996). Yokomizo et al. (1997) cloned the cDNA encoding a cell surface LTB4 receptor that is highly expressed in human leukocytes. Two cDNA clones isolated from retinoic acid-differentiated HL-60 cells contained identical open reading frames encoding a protein of 352 amino acids and predicted to contain 7 membrane-spanning domains, but  
30 different 5-prime untranslated regions. In Chinese hamster ovary (CHO) cells stably expressing this receptor, LTB4 induced increases in intracellular calcium, accumulation of D-myo-inositol-1,4,5-triphosphate, and inhibition of adenylyl cyclase. Furthermore, CHO cells expressing exogenous BLTR showed marked chemotactic responses toward low concentrations of LTB4 in a pertussis-toxin-sensitive manner. Yokomizo et al. (1997) found

that the putative purinoceptor P2Y7 has a primary structure identical to that of one of the BLTR clones, HL-5. To determine whether BLTR also functions as a purinoceptor, they established stable transformants of BLTR in glioma cells that possess negligible amounts of intrinsic purinoceptors. In these cells, up to 300 microM caused no change in intracellular calcium levels, but significant increases in the calcium concentrations were induced by exposure to 10 nanoM LTB4. These results were interpreted to indicate that this receptor is not a purinoceptor, but a BLTR.

The disclosed NOV43 nucleic acid of the invention encoding a P2Y Purinoceptor -like protein includes the nucleic acid whose sequence is provided in Table 43A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 43A while still encoding a protein that maintains its UDP[ Glycosyltransferase -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 37 percent of the bases may be so changed.

The disclosed NOV43 protein of the invention includes the P2Y Purinoceptor -like protein whose sequence is provided in Table 43B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 43B while still encoding a protein that maintains its P2Y Purinoceptor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 62 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this P2Y Purinoceptor -like protein (NOV43) is a member of a "P2Y Purinoceptor family". Therefore, the NOV43 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential

therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing  
 5 (but not limited to) those defined here.

The NOV43 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, Stroke, Tuberos sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-  
 10 telangiectasia, Leukodystrophies, Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, and/or other diseases and pathologies.

NOV43 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV43 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods  
 15 known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV43 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various  
 20 disorders.

#### NOV44

A disclosed NOV44 nucleic acid of 934 nucleotides (also referred to as CG56692-01) encoding a G Protein Coupled Receptor-like protein is shown in Table 44A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 15-17 and ending  
 25 with a TAA codon at nucleotides 921-923. The start and stop codons are shown in bold in Table 44A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 44A. NOV44 nucleotide sequence (SEQ ID NO:167).**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

In a search of public sequence databases, the NOV44 nucleic acid sequence, located on chromosome 7, has 783 of 920 bases (85%) identical to a gb:GENBANK-ID:AB030895|acc:AB030895.1 mRNA from *Mus musculus* (gene for odorant receptor MOR18, complete cds) ( $E = 4.5e^{-146}$ ).

- 5 The disclosed NOV44 polypeptide (SEQ ID NO:168) encoded by SEQ ID NO:167 has 302 amino acid residues and is presented in Table 44B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV44 has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively, NOV44 may also localize to the Golgi body with a certainty of 0.4000, to the endoplasmic
- 10 reticulum (membrane) with a certainty of 0.3000, or to the mitochondrial inner membrane with a certainty of 0.0300. The most likely cleavage site for NOV44 is between positions 39 and 40: VCG-NM.

- 15 A search of sequence databases reveals that the NOV44 amino acid sequence has 257 of 301 amino acid residues (85%) identical to, and 280 of 301 amino acid residues (93%) similar to, the 308 amino acid residue ptnr:SPTREMBL-ACC:Q9R0K2 protein from *Mus musculus* (Mouse) (Odorant Receptor MOR18) ( $E = 5.0e^{-138}$ ).

- NOV44 also has homology to the amino acid sequences shown in the BLASTP data
- 20 listed in Table 44C.

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 44D. In the ClustalW alignment of the NOV44 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

G-protein-coupled receptors (GPCRs) constitute a vast protein family that encompasses a wide range of functions (including various autocrine, paracrine and endocrine processes). They show considerable diversity at the sequence level, on the basis of which they can be separated into distinct groups. We use the term clan to describe the GPCRs, as they embrace a group of families for which there are indications of evolutionary relationship, but between which there is no statistically significant similarity in sequence. The currently known clan members include the rhodopsin-like GPCRs, the secretin-like GPCRs, the cAMP receptors, the fungal mating pheromone receptors, and the metabotropic glutamate receptor family.

The rhodopsin-like GPCRs themselves represent a widespread protein family that includes hormone, neurotransmitter and light receptors, all of which transduce extracellular signals through interaction with guanine nucleotide-binding (G) proteins. Although their activating ligands vary widely in structure and character, the amino acid sequences of the receptors are very similar and are believed to adopt a common structural framework comprising 7 transmembrane (TM) helices

The disclosed NOV44 nucleic acid of the invention encoding a G Protein Coupled Receptor -like protein includes the nucleic acid whose sequence is provided in Table 44A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 44A while still encoding a protein that maintains its UDP[ Glycosyltransferase -like activities and physiological

functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures  
5 include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic  
10 acids, and their complements, up to about 15 percent of the bases may be so changed.

The disclosed NOV44 protein of the invention includes the G Protein Coupled Receptor -like protein whose sequence is provided in Table 44B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 44B while still encoding a protein that maintains its G Protein Coupled  
15 Receptor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 39 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this G Protein Coupled Receptor -like  
20 protein (NOV44) is a member of a "G Protein Coupled Receptor family". Therefore, the NOV44 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug  
25 targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV44 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Systemic lupus erythematosus, Autoimmune disease,  
30 Asthma, Emphysema, Scleroderma, allergy, ARDS, and/or other diseases and pathologies.

NOV44 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV44 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-

NOVX Antibodies" section below. The disclosed NOV44 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV45

A disclosed NOV45 nucleic acid of 994 nucleotides (also referred to as CG56694-01) encoding a Mas Proto-Oncogene-like protein is shown in Table 45A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 17-19 and ending with a TGA codon at nucleotides 980-982. The start and stop codons are shown in bold in Table 45A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 45A. NOV45 nucleotide sequence (SEQ ID NO:169).**

In a search of public sequence databases, the NOV45 nucleic acid sequence, located on chromosome 7, has 353 of 580 bases (60%) identical to a gb:GENBANK-  
ID:I08606|acc:I08606.1 mRNA from Unknown. (Sequence 1 from Patent WO 8707472) (E = 1.2e<sup>-10</sup>).

The disclosed NOV45 polypeptide (SEQ ID NO:170) encoded by SEQ ID NO:169 has 319 amino acid residues and is presented in Table 45B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV45 has no signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6400. Alternatively, NOV45 may also localize to the Golgi body with a certainty of 0.4600, to the endoplasmic reticulum (membrane) with a certainty of 0.3700, or to the endoplasmic reticulum (lumen) with a certainty of 0.1000.

A search of sequence databases reveals that the NOV45 amino acid sequence has 50 of 168 amino acid residues (29%) identical to, and 87 of 168 amino acid residues (51%) similar to, the 378 amino acid residue ptnr:SWISSPROT-ACC:P35410 protein from *Homo sapiens* (Human) (Mas-Related G Protein-Coupled Receptor MRG) ( $E = 5.0e-138$ ).

NOV45 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 45C.

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 45D. In the ClustalW alignment of the NOV45 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

10       The Mas Proto-Oncogene belongs to the family of G-Protein Coupled Receptors. G-protein-coupled receptors (GPCRs) constitute a vast protein family that encompasses a wide range of functions (including various autocrine, paracrine and endocrine processes). They show considerable diversity at the sequence level, on the basis of which they can be separated into distinct groups. We use the term clan to describe the GPCRs, as they embrace a group of

15 families for which there are indications of evolutionary relationship, but between which there is no statistically significant similarity in sequence [1]. The currently known clan members include the rhodopsin-like GPCRs, the secretin-like GPCRs, the cAMP receptors, the fungal mating pheromone receptors, and the metabotropic glutamate receptor family.

20       The human mas oncogene was originally detected by its ability to transform NIH 3T3 cells. We previously showed that the protein encoded by this gene is unique among cellular oncogene products in that it has seven hydrophobic potential transmembrane domains and shares strong sequence similarity with a family of hormone-receptor proteins. We have now cloned the rat homolog of the mas oncogene, determined its DNA sequence, and examined its expression in various rat tissues. A comparison of the predicted sequences of the rat and

25 human mas proteins shows that they are highly conserved, except in their hydrophilic amino-terminal domains. Our examination of the expression of mas, determined by RNA-protection studies, indicates that high levels of mas RNA transcripts are present in the hippocampus and cerebral cortex of the brain, but not in other neural regions or in other tissues. This pattern of expression and the similarity of mas protein to known receptor proteins suggest that mas

30 encodes a receptor that is involved in the normal neurophysiology and/or development of specific neural tissues.

      The rhodopsin-like GPCRs themselves represent a widespread protein family that includes hormone, neurotransmitter and light receptors, all of which transduce extracellular signals through interaction with guanine nucleotide-binding (G) proteins. Although their

35 activating ligands vary widely in structure and character, the amino acid sequences of the receptors are very similar and are believed to adopt a common structural framework comprising 7 transmembrane (TM) helices

      The disclosed NOV45 nucleic acid of the invention encoding a Mas Proto-Oncogene-like protein includes the nucleic acid whose sequence is provided in Table 45A or a fragment

thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 45A while still encoding a protein that maintains its Mas Proto-Oncogene -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 40 percent of the bases may be so changed.

The disclosed NOV45 protein of the invention includes the Mas Proto-Oncogene-like protein whose sequence is provided in Table 45B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 45B while still encoding a protein that maintains its Mas Proto-Oncogene-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 32 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Mas Proto-Oncogene -like protein (NOV45) is a member of a "Mas Proto-Oncogene family". Therefore, the NOV45 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV45 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, Stroke, Tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-

telangiectasia, Leukodystrophies, Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, and/or other diseases and pathologies.

NOV45 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV45 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV45 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV46

NOV46 includes three novel Mas Proto-Oncogene -like proteins disclosed below. The disclosed sequences have been named NOV46a and NOV46b.

#### NOV46a

A disclosed NOV46a nucleic acid of 997 nucleotides (also referred to as CG56696-01) encoding a Mas Proto-Oncogene-like protein is shown in Table 46A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 12-14 and ending with a TGA codon at nucleotides 978-980. The start and stop codons are shown in bold in Table 46A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 46A. NOV46a nucleotide sequence (SEQ ID NO:171).**

In a search of public sequence databases, the NOV46a nucleic acid sequence, located on chromosome 7, has 430 of 705 bases (60%) identical to a gb:GENBANK-ID:MMU249895|acc:AJ249895.1 mRNA from *Mus musculus* (mas proto-oncogene and Igf2r gene for insulin-like growth factor type 2 and L41ps and Au76 pseudogenes) ( $E = 9.3e^{-22}$ ).

The disclosed NOV46a polypeptide (SEQ ID NO:172) encoded by SEQ ID NO:171 has 322 amino acid residues and is presented in Table 46B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV46a has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively, NOV46a may also localize to the Golgi body with a certainty of 0.4000, to the endoplasmic reticulum (membrane) with a certainty of 0.3000, or to the microbody (peroxisome) with a certainty of 0.3000. The most likely cleavage site for NOV46a is between positions 45 and 46: TGN-AV.

**Table 46B. Encoded NOV46a protein sequence (SEQ ID NO:172).**

|                                                                                                                                                                                                                                                                                                                                                   |

10

A search of sequence databases reveals that the NOV46a amino acid sequence has 110 of 275 amino acid residues (40%) identical to, and 175 of 275 amino acid residues (63%) similar to, the 324 amino acid residue ptmr:SWISSPROT-ACC:P12526 protein from *Rattus norvegicus* (Rat) (Mas Proto-Oncogene) ( $E = 1.6e^{-45}$ ).

15

#### NOV46b

In the present invention, the target sequence identified previously, NOV46a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on in silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high

30

redundancy. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated NOV46b. This differs from the previously identified sequence (NOV46a) in having 2 amino acid changes.

A disclosed NOV46b nucleic acid of 964 nucleotides (also referred to as CG56696-02) encoding a Mas-Related G Protein-Coupled Receptor -like protein is shown in Table 46C. An open reading frame was identified beginning with a ACC initiation codon at nucleotides 3-5 and ending with a TGA codon at nucleotides 960-962. The start and stop codons are shown in bold in Table 46C, and the 5' and 3' untranslated regions, if any, are underlined. Because the start codon is not a traditional initiation codon, NOV46b could be a partial reading frame extending further in the 5' direction.

**Table 46C. NOV46b nucleotide sequence (SEQ ID NO:173).**

15

In a search of public sequence databases, the NOV46c nucleic acid sequence, located on chromosome 7, has 381 of 621 bases (61%) identical to a gb:GENBANK-ID:RATMAS|acc:J03823.1 mRNA from *Rattus norvegicus* (Rat mas oncogene, complete cds) ( $E = 9.3e^{-22}$ ).

20

The disclosed NOV46D polypeptide (SEQ ID NO:176) encoded by SEQ ID NO:175 has 330 amino acid residues and is presented in Table 46F using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV46c has a signal peptide and

is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively, NOV46c may also localize to the Golgi body with a certainty of 0.4000, to the endoplasmic reticulum (membrane) with a certainty of 0.3000, or to the microbody (peroxisome) with a certainty of 0.3000. The most likely cleavage site for NOV46c is between positions 65 and 66:  
5 TFS-LY.

**Table 46F. Encoded NOV46c protein sequence (SEQ ID NO:176).**

A search of sequence databases reveals that the NOV46c amino acid sequence has 106 of 279 amino acid residues (37%) identical to, and 166 of 279 amino acid residues (59%) similar to, the 324 amino acid residue ptnr:SWISSPROT-ACC:P12526 protein from *Rattus norvegicus* (Rat) (Mas Proto-Oncogene) ( $E = 1.6e^{-45}$ ).  
10

NOV46c is predicted to be expressed in at least teratocarcinoma cell. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.  
15

In addition, the sequence is predicted to be expressed in hippocampus and brain because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:RATMAS|acc:J03823.1) a closely related Rat mas oncogene, complete cds homolog.

#### NOV46d

A disclosed NOV46d nucleic acid of 1005 nucleotides (also referred to as CG56702-01) encoding a Mas Proto-Oncogene-like protein is shown in Table 46G. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 17-19 and ending with a TGA codon at nucleotides 986-988. The start and stop codons are shown in bold in Table 46G, and the 5' and 3' untranslated regions, if any, are underlined.

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 46J. In the ClustalW alignment of the NOV46 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Table 46K lists the domain description from DOMAIN analysis results against  
 NOV46. This indicates that the NOV46 sequence has properties similar to those of other  
 proteins known to contain this domain.

The Mas Proto Oncogene belongs to the family of G-Protein Coupled Receptors. G-protein-coupled receptors (GPCRs) constitute a vast protein family that encompasses a wide

range of functions (including various autocrine, paracrine and endocrine processes). They show considerable diversity at the sequence level, on the basis of which they can be separated into distinct groups. The currently known clan members include the rhodopsin-like GPCRs, the secretin-like GPCRs, the cAMP receptors, the fungal mating pheromone receptors, and the  
5 metabotropic glutamate receptor family.

The rhodopsin-like GPCRs themselves represent a widespread protein family that includes hormone, neurotransmitter and light receptors, all of which transduce extracellular signals through interaction with guanine nucleotide-binding (G) proteins. Although their activating ligands vary widely in structure and character, the amino acid sequences of the  
10 receptors are very similar and are believed to adopt a common structural framework comprising 7 transmembrane (TM) helices. The human mas oncogene was originally detected by its ability to transform NIH 3T3 cells. We previously showed that the protein encoded by this gene is unique among cellular oncogene products in that it has seven hydrophobic potential transmembrane domains and shares strong sequence similarity with a family of  
15 hormone-receptor proteins. We have now cloned the rat homolog of the mas oncogene, determined its DNA sequence, and examined its expression in various rat tissues. A comparison of the predicted sequences of the rat and human mas proteins shows that they are highly conserved, except in their hydrophilic amino-terminal domains. Our examination of the expression of mas, determined by RNA-protection studies, indicates that high levels of mas  
20 RNA transcripts are present in the hippocampus and cerebral cortex of the brain, but not in other neural regions or in other tissues. This pattern of expression and the similarity of mas protein to known receptor proteins suggest that mas encodes a receptor that is involved in the normal neurophysiology and/or development of specific neural tissues.

The disclosed NOV46 nucleic acid of the invention encoding a Mas Proto-Oncogene-like protein includes the nucleic acid whose sequence is provided in Table 46A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 46A while still encoding a protein that maintains its Mas Proto-Oncogene-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences  
30 are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or

derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 40 percent of the bases may be so changed.

5       The disclosed NOV46 protein of the invention includes the Mas Proto-Oncogene-like protein whose sequence is provided in Table 46B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 46B while still encoding a protein that maintains its Mas Proto-Oncogene-like activities and physiological functions, or a functional fragment thereof. In the mutant or  
10       variant protein, up to about 21 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Mas Proto-Oncogene -like protein (NOV46) is a member of a "Mas Proto-Oncogene family". Therefore, the NOV46 nucleic  
15       acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene  
20       delivery/gene ablation); research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV46 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, Stroke, Tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease,  
25       Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-telangiectasia, Leukodystrophies, Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, and/or other diseases and pathologies.

NOV46 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV46 substances for use in  
30       therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV46 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in

understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV47

A disclosed NOV47 nucleic acid of 523 nucleotides (also referred to as AF152363) encoding a Peptidyl-Prolyl Cis-Trans Isomerase -like protein is shown in Table 47A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 17-19 and ending with a TAA codon at nucleotides 509-511. The start and stop codons are shown in bold in Table 47A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 47A. NOV47 nucleotide sequence (SEQ ID NO:179).**

```

In a search of public sequence databases, the NOV47 nucleic acid sequence, located on chromosome 3, has 523 of 523 bases (100%) identical to a gb:GENBANK-ID:AF152363|acc:AF152363.1 mRNA from *Homo sapiens* (constitutive fragile region FRA3B sequence) ( $E = 5.7e^{-11}$ ).

The disclosed NOV47 polypeptide (SEQ ID NO:180) encoded by SEQ ID NO:179 has 164 amino acid residues and is presented in Table 47B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV47 has no signal peptide and is likely to be localized to the microbody (peroxisome) with a certainty of 0.6400. Alternatively, NOV47 may also localize to the plasma membrane with a certainty of 0.6000, to the cytoplasm with a certainty of 0.4500, or to the mitochondrial matrix space with a certainty of 0.1000.

**Table 47B. Encoded NOV47 protein sequence (SEQ ID NO:180).**

```

A search of sequence databases reveals that the NOV47 amino acid sequence has 141 of 164 amino acid residues (85%) identical to, and 151 of 164 amino acid residues (92%) similar to, the 165 amino acid residue ptnr:pir-id:CSHUA protein from human (peptidylprolyl isomerase (EC 5.2.1.8) A) ( $E = 5.6e^{-75}$ ).

NOV47 is predicted to be expressed in small intestine because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:E02765|acc: E02765.1) a closely related *Sus scrofa* peptidyl-prolyl cis-trans isomerase A sequence homolog.

NOV47 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 47C.

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 47D. In the ClustalW alignment of the NOV47 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 1 percent of the bases may be so changed.

5           The disclosed NOV47 protein of the invention includes the Peptidyl-Prolyl Cis-Trans Isomerase-like protein whose sequence is provided in Table 47B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 47B while still encoding a protein that maintains its Peptidyl-Prolyl Cis-Trans Isomerase-like activities and physiological functions, or a functional fragment  
10       thereof. In the mutant or variant protein, up to about 15 percent of the residues may be so changed.

          The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

          The above disclosed information suggests that this Peptidyl-Prolyl Cis-Trans  
15       Isomerase -like protein (NOV47) is a member of a "Peptidyl-Prolyl Cis-Trans Isomerase family". Therefore, the NOV47 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target  
20       (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

          The NOV47 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in inflammatory bowel disease, diverticular disease, and/or  
25       other diseases and pathologies.

          NOV47 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV47 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-  
30       NOVX Antibodies" section below. The disclosed NOV47 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

**NOV48**

NOV48 includes three novel Phospholipase C Delta-4-like proteins disclosed below.

The disclosed sequences have been named NOV48a and NOV48b.

**NOV48a**

- 5 A disclosed NOV48a nucleic acid of 3238 nucleotides (also referred to as CG56743-01) encoding a Phospholipase C Delta-4-like protein is shown in Table 48A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 370-372 and ending with a TGA codon at nucleotides 2626-2628. The start and stop codons are shown in bold in Table 48A, and the 5' and 3' untranslated regions, if any, are underlined.

15 A search of sequence databases reveals that the NOV48a amino acid sequence has 619 of 752 amino acid residues (82%) identical to, and 675 of 752 amino acid residues (89%) similar to, the 764 amino acid residue ptnr:pir-id:S14113 protein from bovine (1-phosphatidylinositol-4,5-bisphosphate phosphodiesterase (EC 3.1.4.11) delta-2) (E = 0.0).

NOV48a is predicted to be expressed in at least Amygdala, Bone Marrow, Brain,  
 20 Epidermis, Heart, Hypothalamus, Lung, Mammary gland/Breast, Pituitary Gland, Placenta, Retina, Skeletal Muscle, Small Intestine, Stomach. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

25 **NOV48b**

In the present invention, the target sequence identified previously, NOV48a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most

downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on

5 silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra,

10 brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with

15 other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated NOV48b. This differs from the previously

20 identified sequence (NOV48a) in having a deletion of 6 amino acids in one region and one amino acid at another region.

A disclosed NOV48b nucleic acid of 2341 nucleotides (also referred to as CG56743-02) encoding a Phospholipase C Delta-4-like protein is shown in Table 48C. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 55-57 and ending

25 with a TGA codon at nucleotides 2278-2280. The start and stop codons are shown in bold in Table 48C, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 48C. NOV48b nucleotide sequence (SEQ ID NO:183).**

In a search of public sequence databases, the NOV48b nucleic acid sequence, located on chromosome 2, has 1069 of 1075 bases (99%) identical to a gb:GENBANK-

ID:AK023083|acc:AK023083.1 mRNA from *Homo sapiens* (cDNA FLJ13021 fis, clone

5 NT2RP3000742, weakly similar to 1-Phosphatidylinositol-4,5-Bisphosphate

Phosphodiesterase Delta 1 (EC 3.1.4.11)) (E = 0.0).

The disclosed NOV48b polypeptide (SEQ ID NO:184) encoded by SEQ ID NO:183 has 741 amino acid residues and is presented in Table 48D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV48b has no signal peptide and is likely to be localized to the mitochondrial matrix space with a certainty of 0.6523. Alternatively, NOV48b may also localize to the mitochondrial inner membrane with a certainty of 0.3462, to the mitochondrial intermembrane space with a certainty of 0.3462, or to the mitochondrial outer membrane with a certainty of 0.3462.

A search of sequence databases reveals that the NOV48b amino acid sequence has 736 of 741 amino acid residues (99%) identical to, and 737 of 741 amino acid residues (99%)

similar to, the 762 amino acid residue ptrn:TREMBLNEW-ACC:AAH06355 protein from *Homo sapiens* (Human) (Unknown (Protein For MGC:12837)) (E = 0.0).

NOV48b is predicted to be expressed in at least Heart, Stomach, Small Intestine, Bone Marrow, Skeletal Muscle, Brain, Hypothalamus, Pituitary Gland. The sequence is predicted to have the expression pattern of (GENBANK-ID: gb:GENBANK-ID:AK023083|acc:AK023083.1) a closely related *Homo sapiens* cDNA FLJ13021 fis, clone NT2RP3000742, weakly similar to 1-Phosphatidylinositol-4,5-Bisphosphate Phosphodiesterase Delta 1 (EC 3.1.4.11) homolog.

NOV48a also has homology to the amino acid sequences shown in the BLASTP data listed in Table 48E.

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 48F. In the ClustalW alignment of the NOV48 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

gnl|Smart|smart00233, PH, Pleckstrin homology domain.; Domain commonly found in eukaryotic signalling proteins. The domain family possesses multiple functions including the abilities to bind inositol phosphates, and various proteins. PH domains have been found to possess inserted domains (such as in PLC gamma, syntrophins) and to be inserted within other domains. Mutations in Brutons tyrosine kinase (Btk) within its PH domain cause X-linked agammaglobulinaemia (XLA) in patients. Point mutations cluster into the positively charged end of the molecule around the predicted binding site for phosphatidylinositol lipids. (SEQ ID NO:846)

Phosphatidylinositol-specific phospholipase C (EC 3.1.4.11), an eukaryotic intracellular enzyme, plays an important role in signal transduction processes. It catalyzes the hydrolysis of 1-phosphatidyl-D-myo-inositol-3,4,5-triphosphate into the second messenger molecules diacylglycerol and inositol-1,4,5-triphosphate. This catalytic process is tightly regulated by reversible phosphorylation and binding of regulatory proteins. In mammals, there are at least 6 different isoforms of PI-PLC, they differ in their domain structure, their regulation, and their tissue distribution. Lower eukaryotes also possess multiple isoforms of PI-PLC. All eukaryotic PI-PLCs contain two regions of homology, sometimes referred to as 'X-box' and 'Y-box'. The order of these two regions is always the same (NH<sub>2</sub>-X-Y-COOH), but the spacing is variable. In most isoforms, the distance between these two regions is only 50-100 residues but in the gamma isoforms one PH domain, two SH2 domains, and one SH3 domain are inserted between the two PLC-specific domains. The two conserved regions have been shown to be important for the catalytic activity. At the C-terminal of the Y-box, there is a C2 domain possibly involved in Ca-dependent membrane attachment. Phosphoinositide-specific phospholipase C (PLC) mediates the cellular actions of a variety of hormones, neurotransmitters and growth factors. Agonist-dependent activation of PLC causes hydrolysis of membrane phosphatidylinositol 4,5-bisphosphate (PIP<sub>2</sub>), generating the second messengers inositol 1,4,5-trisphosphate (IP<sub>3</sub>) and diacylglycerol (DAG). IP<sub>3</sub> binds specific intracellular receptors to trigger Ca<sup>2+</sup> mobilisation, while DAG mediates activation of a family of protein kinase C isozymes. Based on molecular size, immunoreactivity and amino acid sequence, several subtypes have been classified. In PLC-beta subtypes, X and Y domains are separated by a stretch of 70-120 amino acids rich in Ser, Thr and acidic residues. Their C-terminus is rich in basic residues. In PLC-gammas, there is an insert of more than 400 residues containing an SH3 and two SH2 domains. PLCs show little similarity in the 300-residue N-terminal region preceding the X-domain.

The disclosed NOV48 nucleic acid of the invention encoding a Phospholipase C Delta-4-like protein includes the nucleic acid whose sequence is provided in Table 48A, 48C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 48A or 48C while still encoding a protein that maintains its Phospholipase C Delta-4-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures

include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense  
5 binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 1 percent of the bases may be so changed.

The disclosed NOV48 protein of the invention includes the Phospholipase C Delta-4-like protein whose sequence is provided in Table 48B or 48D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding  
10 residue shown in Table 48B or 48D while still encoding a protein that maintains its Phospholipase C Delta-4-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 28 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or  
15 (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Phospholipase C Delta-4 -like protein (NOV48) is a member of a "Phospholipase C Delta-4 family". Therefore, the NOV48 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The  
20 potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

25 The NOV48 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Cardiomyopathy, Atherosclerosis, Hypertension, Congenital heart defects, Aortic stenosis Atrial septal defect (ASD) ,Atrioventricular (A-V) canal defect, Ductus arteriosus , Pulmonary stenosis , Subaortic stenosis, Ventricular septal defect (VSD), valve diseases, Tuberous sclerosis, Scleroderma, Obesity, Transplantation,  
30 Osteoporosis, Hypercalcaemia, Arthritis, Ankylosing spondylitis, Scoliosis, Von Hippel-Lindau (VHL) syndrome , Alzheimer's disease, Stroke, Tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-telangiectasia, Leukodystrophies, Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, and/or other diseases and pathologies.

NOV48 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV48 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-  
 5 NOVX Antibodies" section below. The disclosed NOV48 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### 10 NOV49

A disclosed NOV49 nucleic acid of 1588 nucleotides (also referred to as CG56739-01) encoding a Leukotriene-B4 Omega- Hydroxylase -like protein is shown in Table 49A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 2-4 and ending with a TGA codon at nucleotides 1577-1579. The start and stop codons are shown  
 15 in bold in Table 49A, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV49 nucleic acid sequence, located on chromosome 19, has 1320 of 1584 bases (83%) identical to a gb:GENBANK-  
 ID:HUMLB4OH|acc:D26480.1 mRNA from *Homo sapiens* (Human mRNA for leukotriene  
 20 B4 omega-hydroxylase, complete cds) ( $E = 9.7e^{-237}$ ).

The disclosed NOV49 polypeptide (SEQ ID NO:186) encoded by SEQ ID NO:185 has 525 amino acid residues and is presented in Table 49B using the one-letter amino acid code.

Signal P, Psort and/or Hydropathy results predict that NOV49 has a signal peptide and is likely to be localized extracellularly with a certainty of 0.8200. Alternatively, NOV49 may also localize to the lysosome (lumen) with a certainty of 0.4520, to the microbody (peroxisome) with a certainty of 0.1611, or to the endoplasmic reticulum (membrane) with a certainty of 0.1000. The most likely cleavage site for NOV49 is between positions 36 and 37: VLA-WT.

**Table 49B. Encoded NOV49 protein sequence (SEQ ID NO:186).**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

A search of sequence databases reveals that the NOV49 amino acid sequence has 397 of 521 amino acid residues (76%) identical to, and 444 of 521 amino acid residues (85%) similar to, the 520 amino acid residue ptmr:SWISSPROT-ACC:Q08477 protein from *Homo sapiens* (Human) (CYTOCHROME P450 4F3 (EC 1.14.13.30) (CYP1B3) (Leukotriene-B4 Omega-Hydroxylase) (Leukotriene-B4 20-Monooxygenase) (Cytochrome P450- LTB-Omega)) ( $E = 4.3e^{-219}$ ).

NOV49 is predicted to be expressed in at least Prostate. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, the sequence is predicted to be expressed in Bone Marrow, Peripheral Blood, Brain, Colon, Coronary Artery, Hippocampus, Kidney, Kidney Cortex, Liver, Lymph node, Pituitary Gland, and Prostate because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:HUMLB4OH|acc:D26480.1) a closely related Human mRNA for leukotriene B4 omega-hydroxylase, complete cds homolog.

NOV49 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 49C.

Table 49C. BLAST results for NOV49

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 49D. In the ClustalW alignment of the NOV49 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Table 49F lists the domain description from DOMAIN analysis results against NOV49. This indicates that the NOV49 sequence has properties similar to those of other proteins known to contain this domain.

gnl|Pfam|pfam00067, p450, Cytochrome P450. Cytochrome P450s are involved in the oxidative degradation of various compounds. Particularly well known for their role in the degradation of environmental toxins and mutagens. Structure is mostly alpha, and binds a heme cofactor. (SEQ ID NO:848)  
CD-Length = 445 residues, 98.9% aligned  
Score = 308 bits (790), Expect = 4e-85

431

Leukotrienes are a group of bioactive compounds that play important roles in such processes as inflammation. Kikuta et al. (1993) (J. Biol. Chem. 268: 9376-9380) isolated a cDNA for the human leukotriene B4 omega-hydroxylase (LTB4H), an enzyme which catalyzes the omega-hydroxylation of leukotriene B4. Their cDNA encoded a 520-amino acid protein with a predicted molecular weight of 59,805 Da. The deduced amino acid sequence contains a cysteine in the conserved heme-binding domain near the C-terminus, which is a characteristic feature of the cytochrome P450 superfamily; the protein shares 31 to 44% similarity with CYP4A, CYP4B, and CYP4C. Kikuta et al. (1993) (J. Biol. Chem. 268: 9376-9380) detected transcript from the LTB4H gene in polymorphonuclear leukocytes and leukocytes. Kikuta et al. (1998) (DNA Cell Biol. 17: 221-230) determined that the CYP4F3 gene contains 13 exons and spans approximately 22.2 kb. By fluorescence in situ hybridization, they mapped the CYP4F3 gene to 19p13.2. The cytochrome P450 enzymes usually act as terminal oxidases in multicomponent electron transfer chains, called P450-containing monooxygenase systems. P450-containing monooxygenase systems primarily fall into two major classes: bacterial/mitochondrial (type I), and microsomal (type II). All P450 enzymes can be categorised into two main groups, the so-called B- and E-classes: P450 proteins of prokaryotic 3-component systems and fungal P450nor (CYP55) belong to the B-class; all other known P450 proteins from distinct systems are of the E-class. This family contains a number of subtypes of both B and E classes.

The disclosed NOV49 nucleic acid of the invention encoding a Leukotriene-B4 Omega- Hydroxylase-like protein includes the nucleic acid whose sequence is provided in Table 49A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 49A while still encoding a protein that maintains its Leukotriene-B4 Omega- Hydroxylase -like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or

variant nucleic acids, and their complements, up to about 17 percent of the bases may be so changed.

The disclosed NOV49 protein of the invention includes the Leukotriene-B4 Omega-Hydroxylase-like protein whose sequence is provided in Table 49B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 49B while still encoding a protein that maintains its Leukotriene-B4 Omega-Hydroxylase-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 25 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Leukotriene-B4 Omega-Hydroxylase-like protein (NOV49) is a member of a "Leukotriene-B4 Omega-Hydroxylase family". Therefore, the NOV49 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV49 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Atherosclerosis, Aneurysm, Hypertension, Fibromuscular dysplasia, Stroke, Scleroderma, Obesity, Transplantation, Myocardial infarction, Embolism, Cardiovascular disorders, Bypass surgery, Osteoporosis, Hypercalcaemia, Arthritis, Ankylosing spondylitis, Scoliosis, Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, Stroke, Tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-telangiectasia, Leukodystrophies, Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, Diabetes, Autoimmune disease, Renal artery stenosis, Interstitial nephritis, Glomerulonephritis, Polycystic kidney disease, Systemic lupus erythematosus, Renal tubular acidosis, IgA nephropathy, Hypercalcaemia, Lesch-Nyhan syndrome, and/or other diseases and pathologies.

NOV49 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV49 substances for use in

therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV49 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV50

NOV50 includes three novel Protein Arginine N-Methyltransferase 2-like proteins disclosed below. The disclosed sequences have been named NOV50a and NOV50b.

### NOV50a

A disclosed NOV50a nucleic acid of 1196 nucleotides (also referred to as CG56771-01) encoding a Protein Arginine N-Methyltransferase 2-like protein is shown in Table 50A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 13-15 and ending with a TGA codon at nucleotides 1068-1070. The start and stop codons are shown in bold in Table 50A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 50A. NOV50a nucleotide sequence (SEQ ID NO:187).**

In a search of public sequence databases, the NOV50a nucleic acid sequence, located on chromosome 19, has 681 of 719 bases (94%) identical to a gb:GENBANK-  
ID:AK001421|acc:AK001421.1 mRNA from *Homo sapiens* (cDNA FLJ10559 fis, clone NT2RP2002618, weakly similar to Protein Arginine N-Methyltransferase 2 (EC 2.1.1.-)) (E = 2.7e<sup>-136</sup>).

The disclosed NOV50a polypeptide (SEQ ID NO:188) encoded by SEQ ID NO:187 has 375 amino acid residues and is presented in Table 50B using the one-letter amino acid

code. Signal P, Psort and/or Hydropathy results predict that NOV50a has no signal peptide and is likely to be localized to the nucleus with a certainty of 0.7000. Alternatively, NOV50a may also localize to the microbody (peroxisome) with a certainty of 0.2641, to the mitochondrial matrix space with a certainty of 0.1000, or to the lysosome (lumen) with a  
 5 certainty of 0.1000.

**Table 50B. Encoded NOV50a protein sequence (SEQ ID NO:188).**

|                                                                                                                                                                                                                                                                                                                                                                                                         |

A search of sequence databases reveals that the NOV50a amino acid sequence has 316  
 of 316 amino acid residues (100%) identical to, and 316 of 316 amino acid residues (100%)  
 10 similar to, the 316 amino acid residue ptnr:SPTREMBL-ACC:Q9NVR8 protein from *Homo sapiens* (Human) (CDNA FLJ10559 FIS, Clone NT2RP2002618, Weakly Similar To Protein Arginine N-Methyltransferase 2 (EC 2.1.1.-)) ( $E = 1.7e^{-169}$ ).

NOV50a is predicted to be expressed in at least lung, bronchus, kidney. This  
 information was derived by determining the tissue sources of the sequences that were included  
 15 in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

#### **NOV50b**

In the present invention, the target sequence identified previously, NOV50a, was  
 subjected to the exon linking process to confirm the sequence. PCR primers were designed by  
 20 starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on in  
 25 silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra,  
 30 brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney,

lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high redundancy. The resulting sequences from all clones were assembled with themselves, with  
 5 other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated NOV50b. This differs from the previously  
 10 identified sequence (NOV50a) at aminoacid position 15 A->G.

A disclosed NOV50b nucleic acid of 1165 nucleotides (also referred to as CG56771-02) encoding a Protein Arginine N-Methyltransferase 2-like protein is shown in Table 50C. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 4-6 and ending with a TGA codon at nucleotides 1129-1131. The start and stop codons are  
 15 shown in bold in Table 50C, and the 5' and 3' untranslated regions, if any, are underlined.

Methyl transfer from S-Adenosyl-L-methionine (SAM) to either nitrogen, oxygen or  
 5 carbon atoms is frequently employed in diverse organisms ranging from bacteria to plants and  
 mammals. The reaction is catalyzed by methyltransferases (MTases) and modifies DNA,  
 RNA, proteins and small molecules like catechol. The catalytic domain of SAM-MTases is of  
 the alpha/beta type with a central mixed beta-sheet around which several alpha-helices are  
 arranged. Topologically it can be divided into two halves. The first half, formed by beta1-  
 10 alphaA-beta2-alphaB-beta3-alphaC, is mainly responsible for SAM binding. The second half,  
 beta4-alphaD-beta5-alphaE-beta6-beta7, is primarily responsible for catalysis. According to  
 the sequential order of these two sites, the SAM-MTases can be divided into three families  
 Protein arginine methylation has been implicated in signal transduction, nuclear transport and  
 transcription regulation. Protein arginine methyltransferases (PRMTs) mediate the AdoMet-  
 15 dependent methylation of many proteins, including many RNA binding proteins involved in  
 various aspects of RNA processing and/or transport.

The bulk of methylated arginine residues in eukaryotic cells are found in  
 heterogeneous nuclear ribonucleoproteins (hnRNPs), RNA-binding proteins that play essential  
 roles in the metabolism of nuclear pre-mRNA. Lin et al. (1996) identified a rat cDNA  
 20 encoding PRMT1 (protein-arginine N-methyltransferase 1; EC 2.1.1.23). Recombinant  
 PRMT1 methylated histones and hnRNP A1 (164017) in vitro. By using a yeast 2-hybrid  
 screen to identify proteins that interact with the intracytoplasmic domain of the interferon-  
 alpha/beta receptor-1 (IFNAR1; 107450), Abramovich et al. (1997) identified a human cDNA  
 encoding a protein that was nearly identical to PRMT1. The deduced 361-amino acid protein  
 25 was designated IR1B4 for 'interferon receptor-1-bound protein 4.' Epitope-tagged IR1B4  
 bound the IFNAR1 intracytoplasmic domain in vitro. Antibodies against IFNAR1  
 coimmunoprecipitated a methyltransferase activity from human cell extracts. An antisense  
 oligonucleotide strongly reduced methyltransferase activity in human cells, and caused them  
 to become more resistant to growth inhibition by interferon. Abramovich et al. (1997)  
 30 concluded that protein methylation, like phosphorylation, may be an important signaling  
 mechanism for certain cytokine receptors. Scott et al. (1998) identified HRMT1L2 transcripts  
 with variable 5-prime ends that encode 3 protein variants with different N-terminal regions.  
 Rat PRMT1 and HRMT1L2 variant 2 (v.2) share 95% sequence identity, but diverge at their N  
 termini. The amino acid sequences of HRMT1L2 and HRMT1L1 (601961) are 27% identical.  
 35 Recombinant protein methylated human hnRNP A1 and a yeast hnRNP in vitro. The  
 HRMT1L2 gene complemented mutations in the yeast hnRNP methyltransferase gene HMT1.

Northern blot analysis revealed that HRMT1L2 is expressed as a predominant 1.4-kb mRNA in various adult and fetal tissues. Additional larger and smaller bands were observed in some tissues.

5 The disclosed NOV50 nucleic acid of the invention encoding a Protein Arginine N-Methyltransferase 2-like protein includes the nucleic acid whose sequence is provided in Table 50A, 50C, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 50A or 50C while still encoding a protein that maintains its Protein Arginine N-Methyltransferase 2-like activities and physiological functions, or a fragment of such a nucleic acid. The invention  
10 further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar  
15 phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 6 percent of the bases may be so changed.

20 The disclosed NOV50 protein of the invention includes the Protein Arginine N-Methyltransferase 2-like protein whose sequence is provided in Table 50B or 50D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 50B or 50D while still encoding a protein that maintains its Protein Arginine N-Methyltransferase 2-like activities and physiological  
25 functions, or a functional fragment thereof. In the mutant or variant protein, up to about 63 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$  that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Protein Arginine N-Methyltransferase 2-like protein (NOV50) is a member of a "Protein Arginine N-Methyltransferase 2 family". Therefore, the NOV50 nucleic acids and proteins identified here  
30 may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target,

antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

- 5           The NOV50 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in systemic lupus erythematosus, autoimmune disease, asthma, emphysema, scleroderma, allergy, ards, diabetes, autoimmune disease, renal artery stenosis, interstitial nephritis, glomerulonephritis, polycystic kidney disease, renal tubular acidosis, IGA nephropathy, hypercalcaemia, Lesch-Nyhan syndrome, and/or other diseases and
- 10           pathologies.

NOV50 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV50 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-  
15   NOVX Antibodies" section below. The disclosed NOV50 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

## 20           NOV51

A disclosed NOV51 nucleic acid of 984 nucleotides (also referred to as CG56759-01) encoding a Olfactory Receptor -like protein is shown in Table 51A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 9-11 and ending with a TAA codon at nucleotides 954-956. The start and stop codons are shown in bold in Table  
25   51A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 51A. NOV51 nucleotide sequence (SEQ ID NO:191).**

In a search of public sequence databases, the NOV51 nucleic acid sequence, located on chromosome 22, has 967 of 984 bases (98%) identical to a gb:GENBANK-

ID:AP000534|acc:AP000534.1 mRNA from *Homo sapiens* (genomic DNA, chromosome 22q11.2, Cat Eye Syndrome region, clone:c23H5) ( $E = 2.9e^{-208}$ ).

- 5 The disclosed NOV51 polypeptide (SEQ ID NO:192) encoded by SEQ ID NO:191 has 315 amino acid residues and is presented in Table 51B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV51 has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6000. Alternatively, NOV51 may also localize to the Golgi body with a certainty of 0.4000, to the endoplasmic
- 10 reticulum (membrane) with a certainty of 0.3000, or to the microbody (peroxisome) with a certainty of 0.3000. The most likely cleavage site for NOV51 is between positions 40 and 41: IYA-LT.

**Table 51B. Encoded NOV51 protein sequence (SEQ ID NO:192).**

|                                                                                                                                                                                                                                                                                                                                          |

|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- 15 A search of sequence databases reveals that the NOV51 amino acid sequence has 191 of 314 amino acid residues (60%) identical to, and 226 of 314 amino acid residues (71%) similar to, the 324 amino acid residue ptrn:SPTREMBL-ACC:Q9WU86 protein from *Mus musculus* (Mouse) (Odorant Receptor S1) ( $E = 7.0e^{-100}$ ).

- 20 NOV51 is predicted to be expressed in at least Apical microvilli of the retinal pigment epithelium, arterial (aortic), basal forebrain, brain, Burkitt lymphoma cell lines, corpus callosum, cardiac (atria and ventricle), caudate nucleus, CNS and peripheral tissue, cerebellum, cerebral cortex, colon, cortical neurogenic cells, endothelial (coronary artery and umbilical vein) cells, palate epithelia, eye, neonatal eye, frontal cortex, fetal hematopoietic cells, heart, hippocampus, hypothalamus, leukocytes, liver, fetal liver, lung, lung lymphoma
- 25 cell lines, fetal lymphoid tissue, adult lymphoid tissue, Those that express MHC II and III nervous, medulla, subthalamic nucleus, ovary, pancreas, pituitary, placenta, pons, prostate, putamen, serum, skeletal muscle, small intestine, smooth muscle (coronary artery in aortic) spinal cord, spleen, stomach, taste receptor cells of the tongue, testis, thalamus, and thymus tissue. This information was derived by determining the tissue sources of the sequences that
- 30 were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

NOV51 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 51C

| Table 51C. BLAST results for NOV51       |                                                                           |                |                 |                  |        |

5 The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 51D. In the ClustalW alignment of the NOV51 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and

10 can potentially be altered to a much broader extent without altering protein structure or function.

G-Protein Coupled Receptor (GPCRs) have been identified as an extremely large family of protein receptors in a number of species. At the phylogenetic level they can be classified into four major subfamilies. These receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors. They are likely to be involved in the recognition and transduction of various signals mediated by G-Proteins, hence their name

G-Protein Coupled Receptors. The human GPCR genes are generally intron-less and belong to four gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

Olfactory receptors (ORs) have been identified as extremely large family of GPCRs in a number of species. As members of the GPCR family, these receptors share a seven transmembrane domain structure with many neurotransmitter and hormone receptors, and are likely to underlie the recognition and G-protein-mediated transduction of odorant signals. Like GPCRs, the ORs they can be expressed in a variety of tissues where they are thought to be involved in recognition and transmission of a variety of signals. The human OR genes are typically intron-less and belong to four different gene subfamilies, displaying great sequence variability. These genes are dominantly expressed in olfactory epithelium.

The disclosed NOV51 nucleic acid of the invention encoding a Olfactory Receptor-like protein includes the nucleic acid whose sequence is provided in Table 51A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 51A while still encoding a protein that maintains its Olfactory Receptor-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 2 percent of the bases may be so changed.

The disclosed NOV51 protein of the invention includes the Olfactory Receptor-like protein whose sequence is provided in Table 51B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 51B while still encoding a protein that maintains its Olfactory Receptor-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 54 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Olfactory Receptor -like protein (NOV51) is a member of a "Olfactory Receptor family". Therefore, the NOV51 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential

5 therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

10 The NOV51 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in developmental diseases, MHCII and III diseases (immune diseases), Taste and scent detectability Disorders, Burkitt's lymphoma, Corticoneurogenic disease, Signal Transduction pathway disorders, Retinal diseases including those involving photoreception, Cell Growth rate disorders; Cell Shape disorders, Feeding

15 disorders; control of feeding; potential obesity due to over-eating; potential disorders due to starvation (lack of appetite), noninsulin-dependent diabetes mellitus (NIDDM1), bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia, asthma, Parkinson's disease, acute heart failure, hypotension,

20 hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety, schizophrenia, manic depression, delirium, dementia, severe mental retardation. Dentatorubro-pallidoluysian atrophy (DRPLA) Hypophosphatemic rickets,

25 autosomal dominant (2) Acrocallosal syndrome and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome and/or other pathologies and disorders of the like.. The polypeptides can be used as immunogens to produce antibodies specific for the invention, and as vaccines. They can also be used to screen for potential agonist and antagonist compounds. For example, a cDNA encoding the OR -like protein may be useful in gene therapy, and the

30 OR-like protein may be useful when administered to a subject in need thereof. By way of nonlimiting example, the compositions of the present invention will have efficacy for treatment of patients suffering from bacterial, fungal, protozoal and viral infections (particularly infections caused by HIV-1 or HIV-2), pain, cancer (including but not limited to Neoplasm; adenocarcinoma; lymphoma; prostate cancer; uterus cancer), anorexia, bulimia,

- asthma, Parkinson's disease, acute heart failure, hypotension, hypertension, urinary retention, osteoporosis, Crohn's disease; multiple sclerosis; and Treatment of Albright Hereditary Osteodystrophy, angina pectoris, myocardial infarction, ulcers, asthma, allergies, benign prostatic hypertrophy, and psychotic and neurological disorders, including anxiety,
- 5 schizophrenia, manic depression, delirium, dementia, severe mental retardation and dyskinesias, such as Huntington's disease or Gilles de la Tourette syndrome, and/or other diseases and pathologies.

- NOV51 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV51 substances for use in
- 10 therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV51 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in
- 15 understanding of pathology of the disease and development of new drug targets for various disorders.

### NOV52

- A disclosed NOV52 nucleic acid of 3828 nucleotides (also referred to as CG56731-01) encoding a H326-like protein is shown in Table 52A. An open reading frame was identified
- 20 beginning with a ATG initiation codon at nucleotides 177-179 and ending with a TAA codon at nucleotides 1968-1970. The start and stop codons are shown in bold in Table 52A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 52A. NOV52 nucleotide sequence (SEQ ID NO:193).**

In a search of public sequence databases, the NOV52 nucleic acid sequence, located on chromosome 22, has 3818 of 3828 bases (99%) identical to a gb:GENBANK-

ID:HSU06631|acc:U06631.1 mRNA from *Homo sapiens* (Human (H326) mRNA, complete cds) (E = 0.0).

The disclosed NOV52 polypeptide (SEQ ID NO:194) encoded by SEQ ID NO:193 has 597 amino acid residues and is presented in Table 52B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV52 has no signal peptide and is likely to be localized to the microbody (peroxisome) with a certainty of 0.3000. Alternatively, NOV52 may also localize to the nucleus with a certainty of 0.3000, to the mitochondrial matrix space with a certainty of 0.1000, or to the lysosome (lumen) with a certainty of 0.1000.

**Table 52B. Encoded NOV52 protein sequence (SEQ ID NO:194).**

A search of sequence databases reveals that the NOV52 amino acid sequence has 588 of 597 amino acid residues (98%) identical to, and 589 of 597 amino acid residues (98%) similar to, the 597 amino acid residue ptnr:SPTREMBL-ACC:Q12839 protein from *Homo sapiens* (Human) (H326) (E = 0.0).

NOV52 is predicted to be expressed in at least adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus, Amnion, Appendix, Bone, Bronchus, Brown adipose, Cervix, Chorionic Villus, Colon, Coronary Artery, Dermis, Epidermis, Foreskin, Hair Follicles, Hypothalamus, Kidney Cortex, Liver, Lung, Lung Pleura, Lymph node, Lymphoid tissue, Muscle, Ovary, Oviduct/Uterine Tube/Fallopian tube, Parathyroid Gland, Parotid Salivary glands, Peripheral Blood, Respiratory Bronchiole, Retina, Right Cerebellum, Skin, Synovium/Synovial membrane, Temporal Lobe, Thymus, Tonsils, Umbilical Vein, Urinary Bladder, Vein, Vulva, Whole Organism.

This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, the sequence is predicted to be expressed in plasma cells (myeloma) because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:HSU06631|acc: U06631.1) a closely related Human (H326) mRNA, complete cds homolog.

NOV52 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 52C

| Table 52C. BLAST results for NOV52          |                                                   |                |                   |                   |        |

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 52D. In the ClustalW alignment of the NOV52 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Beta-transducin (G-beta) is one of the three subunits (alpha, beta, and gamma) of the guanine nucleotide-binding proteins (G proteins) which act as intermediaries in the transduction of signals generated by transmembrane receptors. The alpha subunit binds to and hydrolyzes GTP; the functions of the beta and gamma subunits are less clear but they seem to be required for the replacement of GDP by GTP as well as for membrane anchoring and receptor recognition.

In higher eukaryotes G-beta exists as a small multigene family of highly conserved proteins of about 340 amino acid residues. Structurally G-beta consists of eight tandem repeats of about 40 residues, each containing a central Trp-Asp motif (this type of repeat is also called a WD-40 repeat). Such a repetitive segment has been shown to exist in a number of other proteins, including G-beta-like peptides, yeast STE4, MSI1, CDC4, CDC20, MAK11, PRP4, PWP1 and TUP1, slime-mould AAC3 and coronin, and Drosophila Groucho protein. The number of repeats within these proteins varies between 5 (PRP4, TUP1, and Groucho) and 8 (G-beta, STE4, MSI1, AAC3, CDC4, PWP1, etc.). In G-beta and G-beta like proteins, the repeats span the entire length of the sequence, while in other proteins, they make up the N-terminal, the central or the C-terminal section.

The protein of this invention contains 7 WD-40 repeats. Although the function of this H326-like protein is not precisely known, it has potential importance in the intracellular transduction of signals, similarly to other WD-40 repeat-containing proteins.

The disclosed NOV52 nucleic acid of the invention encoding a H326-like protein includes the nucleic acid whose sequence is provided in Table 52A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 52A while still encoding a protein that maintains its H326-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 1 percent of the bases may be so changed.

The disclosed NOV52 protein of the invention includes the H326-like protein whose sequence is provided in Table 52B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 52B while still encoding a protein that maintains its H326-like activities and physiological  
5 functions, or a functional fragment thereof. In the mutant or variant protein, up to about 36 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this H326 -like protein (NOV52) is a  
10 member of a "H326 family". Therefore, the NOV52 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or  
15 prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV52 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in intracellular transduction of signals and any relevant  
20 diseases that may result from dysregulation of signal transduction, and/or other diseases and pathologies.

NOV52 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV52 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods  
25 known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV52 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various  
30 disorders.

### NOV53

A disclosed NOV53 nucleic acid of 1233 nucleotides (also referred to as CG56745-01) encoding a uracil phosphoribosyltransferase-like protein is shown in Table 53A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 142-144

and ending with a TAA codon at nucleotides 1069-1071. The start and stop codons are shown in bold in Table 53A, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV53 nucleic acid sequence, located on  
5 the X chromosome, has 312 of 544 bases (57%) identical to a gb:GENBANK-ID:

YSCFUR1A|acc: M36485.1 mRNA from *Saccharomyces cerevisiae* (*S.cerevisiae* uracil  
phosphoribosyltransferase (FUR1) gene, complete cds).

The disclosed NOV53 polypeptide (SEQ ID NO:196) encoded by SEQ ID NO:195 has  
309 amino acid residues and is presented in Table 53B using the one-letter amino acid code.  
10 Signal P, Psort and/or Hydropathy results predict that NOV53 has no signal peptide and is  
likely to be localized to the nucleus with a certainty of 0.3000. Alternatively, NOV53 may also  
localize to the mitochondrial matrix space with a certainty of 0.1000, or to the lysosome  
(lumen) with a certainty of 0.1000.

A search of sequence databases reveals that the NOV53 amino acid sequence has 588  
of 597 amino acid residues (98%) identical to, and 138 of 209 amino acid residues (66%)  
identical to, and 165 of 209 amino acid residues (78%) similar to, the 261 amino acid residue  
ptrn:SPTREMBL-ACC:Q9VRQ1 protein from *Drosophila melanogaster* (Fruit fly) (CG5537  
20 Protein) ( $E = 8.5e^{-72}$ ).

NOV53 is predicted to be expressed in at least Bone Marrow, Brain, Bladder, Eye, Cervix, Kidney, Liver, Lymph node, Prostate, Small Intestine, Umbilical Vein. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, and/or RACE sources.

NOV53 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 53C

| Table 53C. BLAST results for NOV53          |                                                                                    |                |                   |                   |        |

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 53D. In the ClustalW alignment of the NOV53 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (i.e., regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

- 5 The gene of invention is a novel uracil phosphoribosyltransferase (UPRT)-like gene. UPRT catalyzes the formation of uridine 5'-monophosphate in the pyrimidine salvage pathway from uracil and 5-phospho-alpha-D-ribose 1-diphosphate. The *Saccharomyces cerevisiae* FUR1 gene encodes UPRT (Kern et al., Gene 88:149-157(1990)). Mutations in the FUR1 gene have been correlated to resistance to 5-fluorouracil, a common chemotherapeutic agent (Kern et al., Curr Genet 1991 May;19(5):333-7).

10 The novel gene belongs to a family of phosphoribosyl transferases, as evidenced by the presence of a characteristic domain. It is anticipated that this gene plays a role in the pyrimidine salvage pathway and that it influences the growth or growth restriction of various tissues, and especially of tumor cells.

- 20 The disclosed NOV53 nucleic acid of the invention encoding a Uracil Phosphoribosyltransferase-like protein includes the nucleic acid whose sequence is provided in Table 53A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 53A while still encoding a protein that maintains its Uracil Phosphoribosyltransferase-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least

in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 43 percent of the bases may be so changed.

5           The disclosed NOV53 protein of the invention includes the Uracil Phosphoribosyltransferase-like protein whose sequence is provided in Table 53B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 53B while still encoding a protein that maintains its Uracil Phosphoribosyltransferase-like activities and physiological functions, or a  
10          functional fragment thereof. In the mutant or variant protein, up to about 4 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Uracil Phosphoribosyltransferase-like protein (NOV53) is a member of a "Uracil Phosphoribosyltransferase family". Therefore,  
15          the NOV53 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to:  
20          protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV53 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease,  
25          stroke, tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral disorders, addiction, anxiety, pain, neurodegeneration, hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, autoimmune disease, allergies, immunodeficiencies, transplantation, graft versus host disease, fertility disorders,  
30          anemia, bleeding disorders, scleroderma, cystitis, incontinence, diabetes, renal artery stenosis, interstitial nephritis, glomerulonephritis, polycystic kidney disease, systemic lupus erythematosus, renal tubular acidosis, IgA nephropathy, hypercalcaemia, cirrhosis, inflammatory bowel disease, diverticular disease, lymphedema, cancer, trauma, tissue degeneration, bacterial/viral/parasitic infections, and/or other diseases and pathologies.

NOV53 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV53 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV53 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### 10 NOV54

NOV54 includes two novel protein phosphatase 2C -like proteins disclosed below. The disclosed sequences have been named NOV54a and NOV54b.

#### NOV54a

A disclosed NOV54a nucleic acid of 2185 nucleotides (also referred to as CG56773-01) encoding a protein phosphatase 2C-like protein is shown in Table 54A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 1-3 and ending with a TGA codon at nucleotides 1402-1404. The start and stop codons are shown in bold in Table 54A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 54A. NOV54a nucleotide sequence (SEQ ID NO:197).**

CCCTATTATTAAATGTTTTCTACAG

In a search of public sequence databases, the NOV54a nucleic acid sequence, located on the p21.1 region of chromosome 3, has 592 of 928 bases (63%) identical to a gb:GENBANK-ID:AK023315|acc:AK023315.1 mRNA from *Homo sapiens* (cDNA FLJ13253 fis, clone OVARC1000751) ( $E = 4.5e^{-41}$ ).

A disclosed NOV54a polypeptide (SEQ ID NO:198) encoded by SEQ ID NO:197 has 467 amino acid residues and is presented in Table 54B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV54a has no signal peptide and is likely to be localized to the microbody (peroxisome) with a certainty of 0.3941. Alternatively, NOV54a may also localize to the nucleus with a certainty of 0.3000, to the lysosome (lumen) with a certainty of 0.1558, or to the mitochondrial matrix space with a certainty of 0.1000.

**Table 54B. Encoded NOV54a protein sequence (SEQ ID NO:198).**

QKEDSLTEEGQVSYYDDVSFVFIPLHSQGQESSDH

A search of sequence databases reveals that the NOV54a amino acid sequence has 32 of 77 amino acid residues (41%) identical to, and 48 of 77 amino acid residues (62%) similar to, the 413 amino acid residue ptmr:SPTREMBL-ACC:Q9M3V1 protein from *Fagus sylvatica* (Beechnut) (Protein Phosphatase 2C (PP2C) (EC 3.1.3.16)) ( $E = 9.2e^{-16}$ ).

NOV54a is predicted to be expressed in at least bone marrow, lymphoid tissue, tonsils, brain, colon, uterus, endometrium, placenta, mammary gland/breast, prostate, testis, foreskin, heart, kidney, lung, spleen, peripheral blood, pituitary gland, retina, and pooled germ cell tumors. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

In addition, the sequence is predicted to be expressed in ovarian carcinoma because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:AK023315|acc:AK023315.1) a closely related *Homo sapiens* cDNA FLJ13253 fis, clone OVARC1000751 homolog.

#### NOV54b

A disclosed NOV54b nucleic acid of 1930 nucleotides (also referred to as CG56773-02) encoding a protein phosphatase 2C-like protein is shown in Table 54C. An open reading

frame was identified beginning with a ATG initiation codon at nucleotides 1-3 and ending with a TGA codon at nucleotides 1147-1149. The start and stop codons are shown in bold in Table 54C, and the 5' and 3' untranslated regions, if any, are underlined.

5 In a search of public sequence databases, the NOV54b nucleic acid sequence, located on chromosome 3, has 446 of 660 bases (67%) identical to a gb:GENBANK-ID:BC011803|acc:BC011803.1 mRNA from *Homo sapiens* (*Homo sapiens*, Similar to RIKEN cDNA 2310008J22 gene, clone MGC:19531 IMAGE:4336762, mRNA, complete cds) (E =  $2.0e^{-56}$ ).

10 The disclosed NOV54b polypeptide (SEQ ID NO:200) encoded by SEQ ID NO:199 has 382 amino acid residues and is presented in Table 54D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV54b has no signal peptide and is likely to be localized to the microbody (peroxisome) with a certainty of 0.4037. Alternatively, NOV54b may also localize to the nucleus with a certainty of 0.3000, to the  
15 lysosome (lumen) with a certainty of 0.1000, or to the mitochondrial matrix space with a certainty of 0.1000.

A search of sequence databases reveals that the NOV54b amino acid sequence has 231 of 270 amino acid residues (85%) identical to, and 244 of 270 amino acid residues (90%) similar to, the 453 amino acid residue ptnr:SPTREMBL-ACC:Q9CSD6 protein from *Mus musculus* (Mouse) (2810423O19RIK Protein) ( $E = 1.6e^{-167}$ ).

NOV54b is predicted to be expressed in at least the following tissues: bone marrow, lymphoid tissue, tonsils, brain, colon, uterus, endometrium, placenta, mammary gland/breast, prostate, testis, foreskin, heart, kidney, lung, spleen, peripheral blood, pituitary gland, retina, and pooled germ cell tumors.

NOV54 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 54E

| Table 54E. BLAST results for NOV54              |                                                                                                                                                  |                |                  |                  |        |

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 54F. In the ClustalW alignment of the NOV54 protein, as

well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Protein phosphorylation plays a key role in the regulation of cellular functions through the activation or inhibition of enzymes involved in various biochemical pathways. Kinases and

phosphatases that determine the phosphorylation state of an enzyme (and its activity) are frequently regulated through the action of hormones and growth factors (1). Four distinct subfamilies of serine/threonine protein phosphatases have been identified in mammals: PP1, PP2A, PP2B and PP2C (2). The PP2C subfamily contains structurally diverse protein  
5 phosphatases with a wide range of functions in cellular signal transduction; however, the exact physiological role of most PP2C enzymes is still unclear.

The protein described in this invention contains protein phosphatase 2C domains and is therefore likely to play a role in signal transduction and cellular proliferation. The protein is also homologous, but not identical, to the rat petrin protein, a PP2C subfamily member that  
10 has been shown to modulate neurite growth inhibition and may therefore be useful in the treatment of nerve damage resulting from traumatic injury, stroke or CNS degenerative disorders (3). The PP2C-like gene described in this invention is also expressed in the brain and may therefore have similar functions in the CNS. However, it is also expressed in a number of other tissues and based on its expression pattern may contribute to additional human diseases,  
15 such as cancer, inflammation/autoimmune diseases, and metabolic disorders. The PP2C-like gene maps to human chromosome 3p21.1.

Protein phosphatase 2C domain is found in protein phosphatase 2C, as well as other proteins e.g. adenylyl cyclase. Protein phosphatase 2C (PP2C) is one of the four major classes of mammalian serine/threonine specific protein phosphatases. PP2C is a monomeric enzyme  
20 of about 42 Kd that shows broad substrate specificity and is dependent on divalent cations (mainly manganese and magnesium) for its activity. Its exact physiological role is still unclear. Three isozymes are currently known in mammals: PP2C- $\alpha$ , - $\beta$  and - $\gamma$ . In yeast, there are at least four PP2C homologs: phosphatase PTC1 that has weak tyrosine phosphatase activity in addition to its activity on serines, phosphatases PTC2 and PTC3, and hypothetical  
25 protein YBR125c. Isozymes of PP2C are also known from *Arabidopsis thaliana* (ABI1, PPH1), *Caenorhabditis elegans* (FEM-2, F42G9.1, T23F11.1), *Leishmania chagasi* and *Paramecium tetraurelia*. In *Arabidopsis thaliana*, the kinase associated protein phosphatase (KAPP) is an enzyme that dephosphorylates the Ser/Thr receptor-like kinase RLK5 and which contains a C-terminal PP2C domain.

30 PP2C does not seem to be evolutionary related to the main family of serine/ threonine phosphatases: PP1, PP2A and PP2B. However, it is significantly similar to the catalytic subunit of pyruvate dehydrogenase phosphatase (PDPC), which catalyzes dephosphorylation and concomitant reactivation of the  $\alpha$  subunit of the E1 component of the pyruvate

dehydrogenase complex. PDPC is a mitochondrial enzyme and, like PP2C, is magnesium-dependent.

The disclosed NOV54 nucleic acid of the invention encoding a Protein phosphatase 2C-like protein includes the nucleic acid whose sequence is provided in Table 54A, 54C or a  
5 fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 54A or 54C while still encoding a protein that maintains its Protein phosphatase 2C-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments  
10 that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical  
15 stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 37 percent of the bases may be so changed.

The disclosed NOV54 protein of the invention includes the Protein phosphatase 2C-like protein whose sequence is provided in Table 54B or 54D. The invention also includes a  
20 mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 54B or 54D while still encoding a protein that maintains its Protein phosphatase 2C-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 56 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  
25  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Protein phosphatase 2C-like protein (NOV54) is a member of a "Protein phosphatase 2C family". Therefore, the NOV54 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The  
30 potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV54 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated cancer, trauma, bacterial and viral infections, in vitro and in vivo regeneration, fertility, endometriosis, hypogonadism, cardiomyopathy, atherosclerosis, hypertension, congenital heart defects, aortic stenosis, atrial septal defect (ASD),

5    atrioventricular (A-V) canal defect, ductus arteriosus, pulmonary stenosis, subaortic stenosis, ventricular septal defect (VSD), valve diseases, tuberous sclerosis, scleroderma, obesity, transplantation, hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, autoimmune disease, allergies, immunodeficiencies, transplantation, graft versus host disease (GVHD), lymphoedema, anemia, Alzheimer's disease, stroke, hypercalcaemia, Parkinson's

10   disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral disorders, addiction, anxiety, pain, neurodegeneration, systemic lupus erythematosus, asthma, emphysema, allergy, ARDS, diabetes, renal artery stenosis, interstitial nephritis, glomerulonephritis, polycystic kidney disease, renal tubular acidosis, IgA nephropathy, hypercalcaemia, Von Hippel-Lindau (VHL)

15   syndrome, endocrine dysfunctions, growth and reproductive disorders, tonsillitis, Hirschsprung's disease, Crohn's Disease, appendicitis, and/or other diseases and pathologies.

NOV54 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV54 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods

20   known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV54 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various

25   disorders.

#### NOV55

A disclosed NOV55 nucleic acid of 1500 nucleotides (also referred to as CG56806-01) encoding a Heparan Sulfate 6-Sulfotransferase 3-like protein is shown in Table 55A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 74-76 and

30   ending with a TGA codon at nucleotides 1490-1492. The start and stop codons are shown in bold in Table 55A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 55A. NOV55 nucleotide sequence (SEQ ID NO:201).**

In a search of public sequence databases, the NOV55 nucleic acid sequence, located on chromosome 13, has 1329 of 1492 bases (89%) identical to a gb:GENBANK-ID:AB024567|acc:AB024567.1 mRNA from *Mus musculus* (mRNA for heparan sulfate 6-sulfotransferase 3, complete cds) ( $E = 7.1e^{-263}$ ).

A disclosed NOV55 polypeptide (SEQ ID NO:202) encoded by SEQ ID NO:201 has 944 amino acid residues and is presented in Table 55B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV55 has a signal peptide and is likely to be localized to the plasma membrane with a certainty of 0.6850. Alternatively, NOV55 may also localize to the endoplasmic reticulum (membrane) with a certainty of 0.6400, to the Golgi body with a certainty of 0.3700, or to the microbody (peroxisome) with a certainty of 0.1269. The most likely cleavage site for NOV55 is between positions 28 and 29: VSP-SC.

**Table 55B. Encoded NOV55 protein sequence (SEQ ID NO:202).**

A search of sequence databases reveals that the NOV55 amino acid sequence has 447 of 472 amino acid residues (94%) identical to, and 458 of 472 amino acid residues (97%)

similar to, the 470 amino acid residue ptnr:SPTREMBL-ACC:Q9QYK4 protein from *Mus musculus* (Mouse) (Heparan Sulfate 6-Sulfotransferase 3) ( $E = 7.5e^{-254}$ ).

NOV55 is predicted to be expressed in at least Right Cerebellum, Oviduct/Uterine Tube/Fallopian tube, Amygdala, and Kidney. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, Public EST sources, Literature sources, and/or RACE sources.

NOV55 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 55C

| Table 55C. BLAST results for NOV55          |                                                                          |                |                  |                  |        |

The homology between these and other sequences is shown graphically in the ClustalW analysis shown in Table 55D. In the ClustalW alignment of the NOV55 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or function.

Heparan-sulfate 6-sulfotransferase (HS6ST) catalyzes the transfer of sulfate from 3'-phosphoadenosine 5'-phosphosulfate to position 6 of the N-sulfoglucosamine residue of heparan sulfate.

The disclosed NOV55 nucleic acid of the invention encoding a Heparan Sulfate 6-Sulfotransferase 3-like protein includes the nucleic acid whose sequence is provided in Table 55A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 55A while still encoding a protein that maintains its Heparan Sulfate 6-Sulfotransferase 3-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The

invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 11 percent of the bases may be so changed.

The disclosed NOV55 protein of the invention includes the Heparan Sulfate 6-Sulfotransferase 3-like protein whose sequence is provided in Table 55B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 55B while still encoding a protein that maintains its Heparan Sulfate 6-Sulfotransferase 3-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 34 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as  $F_{ab}$  or  $(F_{ab})_2$ , that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Heparan Sulfate 6-Sulfotransferase 3-like protein (NOV55) is a member of a "Heparan Sulfate 6-Sulfotransferase 3 family". Therefore, the NOV55 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

The NOV55 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in Diabetes, Autoimmune disease, Renal artery stenosis, Interstitial nephritis, Glomerulonephritis, Polycystic kidney disease, Systemic lupus erythematosus, Renal tubular acidosis, IgA nephropathy, Hypercalcaemia, Lesch-Nyhan syndrome, Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, Stroke, Tuberosclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, Cerebral palsy, Epilepsy, Lesch-Nyhan syndrome, Multiple sclerosis, Ataxia-telangiectasia, Leukodystrophies,

Behavioral disorders, Addiction, Anxiety, Pain, Neuroprotection, and/or other diseases and pathologies.

NOV55 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV55 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV55 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV56

NOV56 includes two novel N-Hydroxyarylamine Sulfotransferase-like proteins disclosed below. The disclosed sequences have been named NOV56a and NOV56b.

#### NOV56a

A disclosed NOV56a nucleic acid of 1223 nucleotides (also referred to as CG56816-01) encoding a N-Hydroxyarylamine Sulfotransferase-like protein is shown in Table 56A. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 2-4 and ending with a TGA codon at nucleotides 974-976. The start and stop codons are shown in bold in Table 56A, and the 5' and 3' untranslated regions, if any, are underlined.

**Table 56A. NOV56a nucleotide sequence (SEQ ID NO:203).**

In a search of public sequence databases, the NOV56a nucleic acid sequence, located on chromosome 2, has 633 of 921 bases (68%) identical to a gb:GENBANK-

ID:AF033653|acc:AF033653.1 mRNA from *Mus musculus* (phenol sulfotransferase mRNA, complete cds) ( $E = 7.3e^{-270}$ ).

A disclosed NOV56a polypeptide (SEQ ID NO:204) encoded by SEQ ID NO:203 has 324 amino acid residues and is presented in Table 56B using the one-letter amino acid code.

- 5 Signal P, Psort and/or Hydropathy results predict that NOV56a has no signal peptide and is likely to be localized to the microbody (peroxisome) with a certainty of 0.7480. Alternatively, NOV56a may also localize to the mitochondrial membrane space with a certainty of 0.1000, or to the lysosome (lumen) with a certainty of 0.1000.

**Table 56B. Encoded NOV56a protein sequence (SEQ ID NO:204).**

A search of sequence databases reveals that the NOV56a amino acid sequence has 155 of 254 amino acid residues (61%) identical to, and 196 of 254 amino acid residues (77%) similar to, the 304 amino acid residue ptnr:SWISSPROT-ACC:P50237 protein from *Rattus norvegicus* (Rat) (N-Hydroxyarylamine Sulfotransferase (EC 2.8.2.-) (HAST-I)) ( $E = 6.7e^{-96}$ ).

15

#### NOV56b

- In the present invention, the target sequence identified previously, NOV56a, was subjected to the exon linking process to confirm the sequence. PCR primers were designed by starting at the most upstream sequence available, for the forward primer, and at the most downstream sequence available for the reverse primer. In each case, the sequence was examined, walking inward from the respective termini toward the coding sequence, until a suitable sequence that is either unique or highly selective was encountered, or, in the case of the reverse primer, until the stop codon was reached. Such primers were designed based on in silico predictions for the full length cDNA, part (one or more exons) of the DNA or protein sequence of the target sequence, or by translated homology of the predicted exons to closely related human sequences sequences from other species. These primers were then employed in PCR amplification based on the following pool of human cDNAs: adrenal gland, bone marrow, brain - amygdala, brain - cerebellum, brain - hippocampus, brain - substantia nigra, brain - thalamus, brain -whole, fetal brain, fetal kidney, fetal liver, fetal lung, heart, kidney, lymphoma - Raji, mammary gland, pancreas, pituitary gland, placenta, prostate, salivary gland, skeletal muscle, small intestine, spinal cord, spleen, stomach, testis, thyroid, trachea, uterus. Usually the resulting amplicons were gel purified, cloned and sequenced to high
- 20  
25  
30

redundancy. The resulting sequences from all clones were assembled with themselves, with other fragments in CuraGen Corporation's database and with public ESTs. Fragments and ESTs were included as components for an assembly when the extent of their identity with another component of the assembly was at least 95% over 50 bp. In addition, sequence traces were evaluated manually and edited for corrections if appropriate. These procedures provide the sequence reported below, which is designated NOV56b. This is identical to the previously identified sequence (NOV56a).

A disclosed NOV56b nucleic acid of 1167 nucleotides (also referred to as CG56816-02) encoding a N-Hydroxyarylamine Sulfotransferase-like protein is shown in Table 56C. An open reading frame was identified beginning with a ATG initiation codon at nucleotides 33-35 and ending with a TGA codon at nucleotides 918-920. The start and stop codons are shown in bold in Table 56C, and the 5' and 3' untranslated regions, if any, are underlined.

In a search of public sequence databases, the NOV56b nucleic acid sequence, located on chromosome 2, has 649 of 919 bases (70%) identical to a gb:GENBANK-ID:AF033653|acc:AF033653.1 mRNA from *Mus musculus* (phenol sulfotransferase mRNA, complete cds) ( $E = 3.6e^{-89}$ ).

The disclosed NOV56b polypeptide (SEQ ID NO:206) encoded by SEQ ID NO:205 has 295 amino acid residues and is presented in Table 56D using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV56b has no signal peptide and is likely to be localized to the microbody (peroxisome) with a certainty of 0.7480. Alternatively, NOV56b may also localize to the mitochondrial membrane space with a certainty of 0.1000, or to the lysosome (lumen) with a certainty of 0.1000.

A search of sequence databases reveals that the NOV56b amino acid sequence has 173  
 of 283 amino acid residues (61%) identical to, and 220 of 283 amino acid residues (77%)  
 similar to, the 304 amino acid residue ptnr:SWISSPROT-ACC:P50237 protein from *Rattus*  
 5 *norvegicus* (Rat) (N-Hydroxyarylamine Sulfotransferase (EC 2.8.2.-) (HAST-I)) ( $E = 4.0e^{-99}$ ).

NOV56b is predicted to be expressed in at least brain. .

NOV56a also has homology to the amino acid sequences shown in the BLASTP data  
 listed in Table 56E

**Table 56E. BLAST results for NOV56a**

10

The homology between these and other sequences is shown graphically in the  
 ClustalW analysis shown in Table 56F. In the ClustalW alignment of the NOV56 protein, as  
 well as all other ClustalW analyses herein, the black outlined amino acid residues indicate  
 regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or  
 15 functional properties), whereas non-highlighted amino acid residues are less conserved and  
 can potentially be altered to a much broader extent without altering protein structure or  
 function.

of IQ, but not appreciably those of 2-amino-1-methyl-6-phenylimidazo[4,5-b]pyridine (PhIP), 2-amino-6-methyldipyrido[1,2-a:3',2'-d]imidazole (Glu-P-I), and 3-amino-1-methyl-5H-pyrido[4,3-b]indole (Trp-P-2). N-Sulfation of heterocyclic amines except IQ was higher in hepatic cytosols of female rats than of male rats. These results suggest the involvement of at least plural forms of sulfotransferase on the N-sulfation. In addition, N-sulfation of IQ was also observed in cytosol of a human liver, suggesting that N-sulfation is one of the metabolic pathways of heterocyclic amines in humans as well as rats. Hepatic sulfotransferase also catalyzes metabolic activation of N-hydroxy derivatives of carcinogenic arylamines. Using anti-HAST (hydroxylarylamine sulfotransferase) antibodies and ST1A1 cDNA as screening probes, several cDNA clones were isolated from the cDNA library. A new member of arylsulfotransferase, ST1C1, whose cDNA shows considerable sequence similarity to ST1A1 cDNA, was found to catalyze O-sulfation of N-hydroxy-2-acetylaminofluorence by the cDNA expression in COS-1 cells. From the close similarity of ontogenic profile and sex-specific expression of ST1C1 and HAST, ST1C1 cDNA was shown to encode a major sulfotransferase (HAST) mediating the metabolic activation of N-hydroxyarylamines in rat livers. In addition, properties of PAPS-dependent N-hydroxyarylamine activation and sulfotransferase in human livers are also discussed.

The disclosed NOV56 nucleic acid of the invention encoding a N-Hydroxyarylamine Sulfotransferase-like protein includes the nucleic acid whose sequence is provided in Table 56A, 56C or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 56A or 56C while still encoding a protein that maintains its N-Hydroxyarylamine Sulfotransferase-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 48 percent of the bases may be so changed.

The disclosed NOV56 protein of the invention includes the N-Hydroxyarylamine Sulfotransferase-like protein whose sequence is provided in Table 56B or 56D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 56B or 56D while still encoding a protein that  
5 maintains its N-Hydroxyarylamine Sulfotransferase-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 32 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

10 The above disclosed information suggests that this N-Hydroxyarylamine Sulfotransferase-like protein (NOV56) is a member of a "N-Hydroxyarylamine Sulfotransferase family". Therefore, the NOV56 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this  
15 invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

20 The NOV56 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in metabolic diseases and disorders, and/or other diseases and pathologies.

NOV56 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV56 substances for use in  
25 therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV56 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in  
30 understanding of pathology of the disease and development of new drug targets for various disorders.

#### NOV57

A disclosed NOV57 nucleic acid of 953 nucleotides (also referred to as CG56829-01) encoding a Testis Specific Serine Kinase-3-like protein is shown in Table 57A. An open

reading frame was identified beginning with a ATG initiation codon at nucleotides 50-52 and ending with a TGA codon at nucleotides 854-856. The start and stop codons are shown in bold in Table 57A, and the 5' and 3' untranslated regions, if any, are underlined.

5 In a search of public sequence databases, the NOV57 nucleic acid sequence, located on chromosome 1, has 831 of 912 bases (91%) identical to a gb:GENBANK-ID:AF201734|acc:AF201734.1 mRNA from *Mus musculus* (testis specific serine kinase-3 (Tssk-3) mRNA, complete cds) ( $E = 2.0e^{-165}$ ).

10 A disclosed NOV57 polypeptide (SEQ ID NO:208) encoded by SEQ ID NO:207 has 268 amino acid residues and is presented in Table 57B using the one-letter amino acid code. Signal P, Psort and/or Hydropathy results predict that NOV57 has no signal peptide and is likely to be localized to the cytoplasm with a certainty of 0.4500. Alternatively, NOV57 may also localize to the microbody (peroxisome) with a certainty of 0.1821, to the mitochondrial matrix space with a certainty of 0.1000, or to the lysosome (lumen) with a certainty of 0.1000.

**Table 57B. Encoded NOV57 protein sequence (SEQ ID NO:208).**

20 A search of sequence databases reveals that the NOV57 amino acid sequence has 240 of 268 amino acid residues (89%) identical to, and 245 of 268 amino acid residues (91%) similar to, the 266 amino acid residue ptnr:SPTREMBL-ACC:Q9JL98 protein from *Mus musculus* (Mouse) (Testis Specific Serine Kinase-3) ( $E = 6.2e^{-124}$ ).

NOV57 is predicted to be expressed in at least lung, testis, B-cell, brain, head and neck. Expression information was derived from the tissue sources of the sequences that were

included in the derivation of the sequence of CuraGen Acc. No. CG56829-01. The sequence is predicted to be expressed in testis because of the expression pattern of (GENBANK-ID: gb:GENBANK-ID:AF201734|acc:AF201734.1) a closely related *Mus musculus* testis specific serine kinase-3 (Tssk-3) mRNA, complete cds homolog.

- 5 NOV57 also has homology to the amino acid sequences shown in the BLASTP data listed in Table 57C

| Table 57C. BLAST results for NOV57          |                                                                                                                                                |                |                  |                  |        |

- The homology between these and other sequences is shown graphically in the
- 10 ClustalW analysis shown in Table 57D. In the ClustalW alignment of the NOV57 protein, as well as all other ClustalW analyses herein, the black outlined amino acid residues indicate regions of conserved sequence (*i.e.*, regions that may be required to preserve structural or functional properties), whereas non-highlighted amino acid residues are less conserved and can potentially be altered to a much broader extent without altering protein structure or
- 15 function.

Eukaryotic protein kinases (1) are enzymes that belong to a very extensive family of proteins which share a conserved catalytic core common with both serine/threonine and tyrosine protein kinases. Protein phosphorylation is a fundamental process for the regulation of cellular functions. The coordinated action of both protein kinases and phosphatases controls the levels of phosphorylation and, hence, the activity of specific target proteins. One of the predominant roles of protein phosphorylation is in signal transduction, where extracellular signals are amplified and propagated by a cascade of protein phosphorylation and dephosphorylation events. Two of the best characterized signal transduction pathways involve the cAMP-dependent protein kinase and protein kinase C (PKC). Each pathway uses a different second-messenger molecule to activate the protein kinase, which, in turn, phosphorylates specific target molecules. Extensive comparisons of kinase sequences defined a common catalytic domain, ranging from 250 to 300 amino acids. This domain contains key amino acids conserved between kinases and are thought to play an essential role in catalysis. In the N-terminal extremity of the catalytic domain there is a glycine-rich stretch of residues in the vicinity of a lysine residue, which has been shown to be involved in ATP binding. In the

central part of the catalytic domain there is a conserved aspartic acid residue which is important for the catalytic activity of the enzyme (2).

Protein kinases and phosphatases regulate cell-cycle progression, transcription, translation, protein sorting and cell adhesion events that are critical to the inflammatory  
5 process. Two of the best-characterized immunosuppressants, cyclosporin and rapamycin, are also effective anti-inflammatory drugs. They act directly on protein phosphorylation and, as such, validate the concept that small-molecule modulators of phosphorylation cascades possess anti-inflammatory properties (3).

Some examples of the role of serine/threonine protein kinases that are important in cell  
10 proliferation and disease include AKT, RAF1 and PIM1. Dudek et al. (4) demonstrated that AKT is important for the survival of cerebellar neurons. Thus, the 'orphan' kinase moved center stage as a crucial regulator of life and death decisions emanating from the cell membrane. Holland et al. (5) transferred, in a tissue-specific manner, genes encoding activated forms of Ras and Akt to astrocytes and neural progenitors in mice. These authors  
15 found that although neither activated Ras nor Akt alone was sufficient to induce glioblastoma multiforme (GBM) formation, the combination of activated Ras and Akt induced high-grade gliomas with the histologic features of human GBMs. These tumors appeared to arise after gene transfer to neural progenitors, but not after transfer to differentiated astrocytes. Increased activity of Ras is found in many human GBMs and Akt activity is increased in most of these  
20 tumors, implying that combined activation of these 2 pathways accurately models the biology of this disease (5).

Another disease that involves yet another serine/threonine kinase is Peutz-Jeghers syndrome (PJS), an autosomal dominant disorder characterized by melanocytic macules of the lips, buccal mucosa, and digits, multiple gastrointestinal hamartomatous polyps, and an  
25 increased risk of various neoplasms. Jenne et al. (6) identified and characterized the serine/threonine kinase STK11 and identified mutations in PJS patients. All 5 germline mutations were predicted to disrupt the function of the kinase domain. They concluded that germline mutations in STK11, probably in conjunction with acquired genetic defects of the second allele in somatic cells according to the Knudson model, caused the manifestations of  
30 PJS. These authors commented that PJS was the first cancer susceptibility syndrome identified that is due to inactivating mutations in a protein kinase and found mutations in the STK11 gene in 11 of 12 unrelated families with PJS. Ten of the 11 were truncating mutations. All were heterozygous in the germline. Su et al. (7) found that of 53 PJS patients with cancer reported to that time, 6 (11%) were diagnosed with pancreatic adenocarcinoma. Su et al. (7)

presented evidence that the STK11 gene plays a role in the development of both sporadic and familial (PJS) pancreatic and biliary cancers. They found that in sporadic cancers, the STK11 gene was somatically mutated in 5% of pancreatic cancers and in at least 6% of biliary cancers examined. In the patient with pancreatic cancer associated with PJS, there was inheritance of a mutated copy of the STK11 gene and somatic loss of the remaining wildtype allele.

The novel human serine/threonine protein kinase of the invention contains a protein kinase domain. Therefore it is anticipated that this novel protein has a role in the regulation of essentially all cellular functions and could be a potentially important target for drugs. Such drugs may have important therapeutic applications, such as treating numerous inflammatory diseases.

The disclosed NOV57 nucleic acid of the invention encoding a Testis Specific Serine Kinase-3-like protein includes the nucleic acid whose sequence is provided in Table 57A or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 57A while still encoding a protein that maintains its Testis Specific Serine Kinase-3-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of nonlimiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 9 percent of the bases may be so changed.

The disclosed NOV57 protein of the invention includes the Testis Specific Serine Kinase-3-like protein whose sequence is provided in Table 57B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 57B while still encoding a protein that maintains its Testis Specific Serine Kinase-3-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 53 percent of the residues may be so changed.

The invention further encompasses antibodies and antibody fragments, such as F<sub>ab</sub> or (F<sub>ab</sub>)<sub>2</sub>, that bind immunospecifically to any of the proteins of the invention.

The above disclosed information suggests that this Testis Specific Serine Kinase-3-like protein (NOV57) is a member of a "Testis Specific Serine Kinase-3 family". Therefore, the NOV57 nucleic acids and proteins identified here may be useful in potential therapeutic applications implicated in (but not limited to) various pathologies and disorders as indicated below. The potential therapeutic applications for this invention include, but are not limited to: protein therapeutic, small molecule drug target, antibody target (therapeutic, diagnostic, drug targeting/cytotoxic antibody), diagnostic and/or prognostic marker, gene therapy (gene delivery/gene ablation), research tools, tissue regeneration *in vivo* and *in vitro* of all tissues and cell types composing (but not limited to) those defined here.

10       The NOV57 nucleic acids and proteins of the invention are useful in potential therapeutic applications implicated in metabolic diseases and disorders, and/or other diseases and pathologies.

NOV57 nucleic acids and polypeptides are further useful in the generation of antibodies that bind immuno-specifically to the novel NOV57 substances for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below. The disclosed NOV57 protein has multiple hydrophilic regions, each of which can be used as an immunogen. These novel proteins can be used in assay systems for functional analysis of various human disorders, which will help in understanding of pathology of the disease and development of new drug targets for various disorders.

## NOV58

NOV58 includes two Gap Junction Beta-5-like proteins, designated herein as NOV58a and NOV58b. Gap junctions are conduits that allow the direct cell-to-cell passage of small cytoplasmic molecules, including ions, metabolic intermediates, and second messengers, and that thereby mediate intercellular metabolic and electrical communication. Gap junction channels consist of connexin protein subunits, which are encoded by a multigene family.

### NOV58a

30       The disclosed NOV58a (alternatively referred to herein as CG56315-01) includes the 728 nucleotide sequence (SEQ ID NO:209) shown in Table 58A. A NOV58a ORF begins with a Kozak consensus ATG initiation codon at nucleotides 28-30 and ends with a stop codon at nucleotides 697-699. The disclosed NOV58a maps to human chromosome 6.

A NOV58a polypeptide (SEQ ID NO:210) encoded by SEQ ID NO:209 is 223 amino  
5 acids in length and is presented using the one-letter amino acid code in Table 58B. The Psort  
profile for NOV58a predicts that this sequence has a signal peptide and is likely to be  
localized at the plasma membrane with a certainty of 0.6000. In alternative embodiments, a  
NOV58a polypeptide is located to the mitochondrial inner membrane with a certainty of  
0.4358, to the endoplasmic reticulum (membrane) with a certainty of 0.3000, or to the Golgi  
10 with a certainty of 0.4000. The Signal P predicts a likely cleavage site for a NOV58a peptide  
is between positions 40 and 41, *i.e.*, at the dash in the sequence VAA-EH.

#### NOV58b

15 The disclosed NOV58b (alternatively referred to herein as CG56315-02) includes the  
727 nucleotide sequence (SEQ ID NO:211) shown in Table 58C. A SEC2 ORF begins with a  
Kozak consensus ATG initiation codon at nucleotides 27-29 and ends with a stop codon at  
nucleotides 696-698. The disclosed NOV58b maps to human chromosome 10.

- 15 In a search of public sequence databases, it was found, for example, that the nucleic acid sequence of this invention has 240 of 336 bases (71%) identical to a gb:GENBANK-ID:RATCXN311A|acc:M76533.1 mRNA from *Rattus norvegicus* (*Rattus norvegicus* connexin (CXN-311) gene). The full amino acid sequence of the protein of the invention was

found to have 125 of 220 amino acid residues (56%) identical to, and 170 of 220 amino acid residues (77%) similar to, the 271 amino acid residue ptnr:SWISSNEW-ACC:Q02739 protein from *Mus musculus* (Mouse) (GAP JUNCTION BETA-5 PROTEIN (CONNEXIN 31.1) (CX31.1)). NOV58 also has homology to the other proteins shown in the BLASTP data in

5 Table 58F.

| Table 58F. NOV58 BLASTP results                |                                                                                        |             |                 |                 |        |

The presence of identifiable domains in NOV58 was determined by searches using software algorithms such as PROSITE, DOMAIN, Blocks, Pfam, ProDomain, and Prints, and then determining the Interpro number by crossing the domain match (or numbers) using the

5 Interpro website (<http://www.ebi.ac.uk/interpro>). DOMAIN results for NOV58 as disclosed in Table 58H, were collected from the Conserved Domain Database (CDD) with Reverse Position Specific BLAST analyses. This BLAST analysis software samples domains found in the Smart and Pfam collections. For Table 58H fully conserved single residues are indicated by the sign (!) and "strong" semi-conserved residues are indicated by the sign (+). The

10 "strong" group of conserved amino acid residues may be any one of the following groups of amino acids: STA, NEQK, NHQK, NDEQ, QHRK, MILV, MILF, HY, FYW.

Table 58H lists the domain description from DOMAIN analysis results against NOV58. This indicates that the NOV58 sequence has properties similar to those of other proteins known to contain this domain.

Connexins are a family of integral membrane proteins that oligomerise to form intercellular channels that are clustered at gap junctions. These channels are specialized sites of cell-cell contact that allow the passage of ions, intracellular metabolites and messenger molecules (with molecular weight <1-2 kD) from the cytoplasm of one cell to its apposing neighbours. They are found in almost all vertebrate cell types, and somewhat similar proteins have been cloned from plant species. Invertebrates utilise a different family of molecules, innexins, that share a similar predicted secondary structure to the vertebrate connexins, but have no sequence identity to them.

Vertebrate gap junction channels are thought to participate in diverse biological functions. For instance, in the heart they permit the rapid cell-cell transfer of action potentials, ensuring coordinated contraction of the cardiomyocytes. They are also responsible for neurotransmission at specialised 'electrical' synapses. In non-excitable tissues, such as the liver, they may allow metabolic cooperation between cells. In the brain, glial cells are extensively-coupled by gap junctions; this allows waves of intracellular Ca<sup>2+</sup> to propagate through nervous tissue, and contribute to their ability to spatially-buffer local changes in extracellular K<sup>+</sup> concentration.

The connexin protein family is encoded by at least 13 genes in rodents, with many homologues cloned from other species. They show overlapping tissue expression patterns, most tissues expressing more than one connexin type. Their conductances, permeability to different molecules, phosphorylation and voltage-dependence of their gating, have been found to vary. Possible communication diversity is increased further by the fact that gap junctions may be formed by the association of different connexin isoforms from apposing cells.

However, in vitro studies have shown that not all possible combinations of connexins produce active channels.

Hydropathy analysis predicts that all cloned connexins share a common transmembrane (TM) topology. Each connexin is thought to contain 4 TM domains, with two extracellular and three cytoplasmic regions. This model has been validated for several of the family members by in vitro biochemical analysis. Both N- and C-termini are thought to face the cytoplasm, and the third TM domain has an amphipathic character, suggesting that it contributes to the lining of the formed-channel. Amino acid sequence identity between the isoforms is ~50-80%, with the TM domains being well conserved. Both extracellular loops contain characteristically conserved cysteine residues, which likely form intramolecular disulphide bonds. By contrast, the single putative intracellular loop (between TM domains 2 and 3) and the cytoplasmic C-terminus are highly variable among the family members. Six connexins are thought to associate to form a hemi-channel, or connexon. Two connexons then interact (likely via the extracellular loops of their connexins) to form the complete gap junction channel. Two sets of nomenclature have been used to identify the connexins. The first, and most commonly used, classifies the connexin molecules according to molecular weight, such as connexin43 (abbreviated to Cx43), indicating a connexin of molecular weight close to 43 kD. However, studies have revealed cases where clear functional homologues exist across species that have quite different molecular masses; therefore, an alternative nomenclature was proposed based on evolutionary considerations, which divides the family into two major subclasses, alpha and beta, each with a number of members.

Due to their ubiquity and overlapping tissue distributions, it has proved difficult to elucidate the functions of individual connexin isoforms. To circumvent this problem, particular connexin-encoding genes have been subjected to targeted-disruption in mice, and the phenotype of the resulting animals investigated. Around half the connexin isoforms have been investigated in this manner. Further insight into the functional roles of connexins has come from the discovery that a number of human diseases are caused by mutations in connexin genes. For instance, mutations in Cx32 give rise to a form of inherited peripheral neuropathy called X-linked dominant Charcot-Marie-Tooth disease. Similarly, mutations in Cx26 are responsible for both autosomal recessive and dominant forms of nonsyndromic deafness, a disorder characterised by hearing loss, with no apparent effects on other organ systems.

The disclosed NOV58 is a connexin-like protein localized to gap junctions. Gap junctions were first characterized by electron microscopy as regionally specialized structures

on plasma membranes of contacting adherent cells. These structures were shown to consist of cell-to-cell channels. Proteins, called connexins, purified from fractions of enriched gap junctions from different tissues differ. The connexins are designated by their molecular mass. Another system of nomenclature divides gap junction proteins into 2 categories, alpha and beta, according to sequence similarities at the nucleotide and amino acid levels. For example, CX43 is designated alpha-1 gap junction protein, whereas CX32 and CX26 are called beta-1 and beta-2 gap junction proteins, respectively. This nomenclature emphasizes that CX32 and CX26 are more homologous to each other than either of them is to CX43.

Willecke et al. (1990) used rat connexin gene probes in Southern blot analysis of human-mouse somatic cell hybrids to map the CX26 gene to chromosome 13. By means of somatic cell hybrids, Hsieh et al. (1991) assigned the GJB2 gene to chromosome 13 in man and chromosome 14 in the mouse. Haefliger et al. (1992) showed that the rat homologs of the CX26 and CX46 genes are tightly linked on chromosome 14. By isotopic in situ hybridization, Mignon et al. (1996) mapped GJB2 to 13q11-q12 and confirmed the assignment to mouse chromosome 14. Kelsell et al. (1997) studied a pedigree containing individuals with autosomal dominant deafness and identified a mutation in the CX26 gene: a 101T-C transition resulting in a met34-to-thr amino acid substitution. CX26 mutations resulting in premature stop codons were also found in 3 autosomal recessive nonsyndromic sensorineural deafness pedigrees, genetically linked to 13q11-q12, where the CX26 gene is localized.

Immunohistochemical staining of human cochlear cells for CX26 demonstrated high levels of expression. Kelley et al. (1998) presented evidence that the 101T-C missense mutation identified by Kelsell et al. (1997) in individuals with autosomal dominant nonsyndromic deafness is not sufficient to cause hearing loss. Carrasquillo et al. (1997) performed linkage analysis in 2 interrelated inbred kindreds in a single Israeli-Arab village containing more than 50 individuals with nonsyndromic recessive deafness. Genetic mapping demonstrated that a gene located at 13q11 (DFNB1) segregated with the deafness in these 2 kindreds. Haplotype analysis, using 8 microsatellite markers spanning 15 cM in 13q11, suggested the segregation of 2 different mutations in this extended kindred; affected individuals were homozygotes for either haplotype or compound heterozygotes. Carrasquillo et al. (1997) identified 2 distinct mutations, trp77 to arg and 35delG, in the CX26 gene, both of which were predicted to inactivate connexin 26.

The recombination of marker alleles involving polymorphisms in 13q11, at known map distances from the mutations, allowed them to estimate the age of the mutations to be 3 to 5 generations (75 to 125 years). The study demonstrated that in small populations with high

rates of consanguinity, as compared with large outbred populations, recessive mutations may have very recent origin and show allelic diversity. They pointed to the same phenomenon being observed for Hurler syndrome with 3 unique mutations and for metachromatic leukodystrophy with 5 distinct mutations, discovered among the Druze and Muslim Arab villages in Israel. In light of these findings, the authors commented that it is likely that homozygosity mapping studies in highly inbred communities may be compromised, as may be studies of mapping by linkage disequilibrium, unless the possibility of mutational diversity is taken into account.

Lench et al. (1998) studied the role of CX26 mutations in singleton (sporadic) cases of nonsyndromal sensorineural deafness. Such mutations were identified in 4 of 43 U.K. and 2 of 25 Belgian patients. Thus, about 10% of families presenting with a child sporadically affected with this disorder can be offered definitive mendelian recurrence risks. This was said to be the first genetic test available for screening such children. Kelley et al. (1998) analyzed 58 multiplex families each having at least 2 affected children diagnosed with autosomal recessive nonsyndromic deafness. Mutations in both alleles of GJB2 were observed in 20 of the 58 families. A 30delG allele occurred in 33 of the 116 chromosomes, for a frequency of 0.284. This mutation was observed in 2 of 192 control chromosomes, for an estimated gene frequency of  $0.01 \pm 0.007$ . The homozygous frequency of the 30delG allele was then estimated at 0.0001, or 1 in 10,000. Given that the frequency of all childhood hearing impairment is 1 in 1,000 and that half of that is genetic, the specific mutation 30delG is responsible for 10% of all childhood hearing loss and for 20% of all childhood hereditary hearing loss. Six novel mutations were also observed in the affected population.

Murgia et al. (1999) studied 53 unrelated individuals with nonsyndromic sensorineural hearing impairment and carried out CX26 mutation analysis. Mutations were found in 53% of cases, in 35.3% of those in whom autosomal recessive inheritance was thought likely and in 60% of the presumed sporadic cases. Three novel mutations were found. The hearing deficit varied from mild to profound even within the same family. Among patients with profound hearing loss, 35.5% were found to have a mutation; among those severely impaired, 20%; and among those moderately impaired, 33.3%.

Rabionet et al. (2000) analyzed the GJB2 gene in 576 families/unrelated patients with recessive or sporadic deafness from Italy and Spain, 193 of them being referred as autosomal recessive and the other 383 as apparently sporadic. Of the 1,152 unrelated GJB2 chromosomes, 37% had GJB2 mutations. A total of 23 different mutations were detected. Mutation 35delG was the most common, accounting for 82% of all GJB2 deafness alleles. It

represented 88% of the alleles in Italian patients and only 55% in Spanish cases. Sobe et al. (2000) sequenced the entire coding region of the GJB2 gene in 75 hearing-impaired children and adults in Israel. Was both prelingual and postlingual, with hearing loss ranging from moderate to profound. Almost 39% of all persons tested harbored GJB2 mutations, most of which were 35delG and 167delT. A novel mutation, involving both a deletion and an insertion, 51del12insA, was identified in a family originating from Uzbekistan. All GJB2 mutations were associated with prelingual hearing loss, although severity ranged from moderate to profound, with variability even among hearing-impaired sibs. No significant difference in hearing levels was found between individuals with 35delG and 167delT mutations.

Antoniadi et al. (2000) screened 26 unrelated Greek patients with prelingual sensorineural deafness in whom syndromic forms and environmental causes of deafness had been excluded. They detected the 35delG mutation in 28 chromosomes (53.8%); another 3 sequence variations accounted for 7.6% of the alleles. Wilcox et al. (2000) performed mutation analysis of the GJB2 gene and audiology on 106 families presenting with at least 1 child with congenital hearing loss. In 74 families (80 children), the etiology was consistent with nonsyndromic recessive hearing loss. Six different GJB2 mutations, including 1 novel mutation, were identified. They found that GJB2 mutations caused a range of phenotypes from mild to profound hearing impairment and that loss of hearing in the high-frequency range (4,000 to 8,000 Hz) is a characteristic feature in children with molecularly diagnosed CX26 hearing impairment. They also demonstrated that high frequency hearing loss was found in a group of similar size of deaf children in whom a mutation could be found in only one of the GJB2 alleles. In their study, the M34T mutation was associated with hearing loss only when present in compound heterozygous state, suggesting autosomal recessive inheritance. Heathcote et al. (2000) reported a missense mutation in affected members of a family with autosomal dominant deafness and palmoplantar keratoderma. Rabionet et al. (2000) reviewed the molecular genetics of hearing impairment due to mutations in gap junction genes encoding beta-connexins. Among these genes, mutations in GJB2 account for about 50% of all congenital cases of hearing impairment. Three mutations in GJB2 are particularly common in specific populations: 35delG in Caucasoids, 167delT in Ashkenazi Jews, and 235delC in Orientals. Carrier frequencies in these populations vary between 1 and 30 and 1 in 75. Over 50 mutations have been identified in the GJB2 gene, of which some missense changes have a dominant-negative action in hearing impairment, with partial to full penetrance. Functional studies for some missense mutations in connexins 26, 30, and 32 indicate abnormal gap junction conductivity. Expression patterns in mouse and rat cochlea indicate that connexin 26

and connexin 30 are expressed in the supporting cells of the cochlea, suggesting a potential role in endolymph potassium recycling.

In the Japanese population, Kudo et al. (2000) sequenced the GJB2 gene in 39 patients with prelingual deafness, 39 patients with postlingual progressive sensorineural hearing loss, and 63 individuals with normal hearing. GJB2 mutations were found in 5 of the 39 patients (12%) with prelingual deafness. The most common mutation was 235delC observed in 7 of 10 mutant alleles. There were no cases with the 30delG allele. No GJB2 mutation was found in patients in the postlingual hearing loss group. Nance et al. (2000) noted that recessive mutations at the connexin-26 gene locus account for nearly half of all cases of genetic deafness in many populations. They suggested that this high frequency is only seen in populations with a long tradition of intermarriage among deaf people. Available data are consistent with the hypothesis that such marriages might well have contributed to the high frequency of connexin-26 deafness in the U.S., and could represent a novel mechanism for maintaining specific genotypes at unexpectedly high frequencies.

The NOV58 disclosed in this invention is predicted to be expressed in at least the following tissues: brain, lung, ovary, and colon. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV58 is provided in Example 2.

The nucleic acids and proteins of NOV58 are useful in potential therapeutic applications implicated in various gap junction-related pathological disorders described further herein. The NOV58 nucleic acid encoding the connexin-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. The novel nucleic acid of the invention encoding a Connexin-like protein includes the nucleic acid whose sequence is provided in Table 58A or 58C, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 58A or 58C while still encoding a protein that maintains its connexin-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to the sequence shown in Table 58A or 58C, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids

whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 29% of the bases may be so changed. The novel protein of the invention includes the connexin-like protein whose sequence is provided in Table 58B or 58D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 58B or 58D while still encoding a protein that maintains its connexin-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 44% of the amino acid residues may be so changed.

These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

### NOV59

A eukaryotic translation initiation factor 5 (EIF5), disclosed herein as NOV59, interacts with the 40S initiation complex to promote hydrolysis of bound GTP with concomitant joining of the 60S ribosomal subunit to the 40S initiation complex. The resulting functional 80S ribosomal initiation complex is then active in peptidyl transfer and chain elongations. The disclosed NOV59 (alternatively referred to herein as CG56633-01) includes the 1328 nucleotide sequence (SEQ ID NO:213) shown in Table 59A. A NOV59 ORF begins with a Kozak consensus ATG initiation codon at nucleotides 34-36 and ends with a TGA codon at nucleotides 1273-1275. The disclosed NOV59 maps to human chromosome 3.

- A BLAST analysis of NOV59 was run against the proprietary PatP GENESEQ Protein
- 10 Patent database. It was found, for example, that the amino acid sequence of NOV59 had high homology to other proteins as shown in Table 59C.

**Table 59C. BLASTX results from PatP database for NOV59**

| Smallest                                        |                                          | High Score | Sum Probability P(N) |

- In a search of sequence databases, it was found, for example, that the nucleic acid
- 15 sequence of this invention has 778 of 824 bases (94%) identical to a gb:GENBANK-ID:HUMRSC419|acc:D13630.1 mRNA from *Homo sapiens* (Human mRNA for KIAA0005 gene. The full amino acid sequence of the protein of the invention was found to have 372 of

419 amino acid residues (88%) identical to, and 385 of 419 amino acid residues (91%) similar to, the 419 amino acid residue ptnr:SPTREMBL-ACC:Q15394 protein from *Homo sapiens* (Human) (KIAA0005 PROTEIN). NOV59 also has homology to the other proteins shown in the BLASTP data in Table 59D.

The NOV59 disclosed in this invention is predicted to be expressed in at least the following tissues: brain. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV59 is provided in Example 2.

The nucleic acids and proteins of NOV59 are useful in potential therapeutic applications implicated in various pathological disorders described further herein, for example, Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, stroke, tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral disorders, addiction, anxiety, pain, myasthenia gravis, neuroprotection, endocrine dysfunctions, diabetes, obesity, growth and reproductive disorders and other diseases, disorders and conditions of the like. The NOV59 nucleic acid encoding the translation initiation factor 5-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. The novel nucleic acid of the invention encoding a translation initiation factor 5-like protein includes the nucleic acid whose sequence is provided in Table 59A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 59A while still encoding a protein that maintains its translation initiation factor 5-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures

include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense  
 5 binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 6% of the residues may be so changed.

The novel protein of the invention includes the translation initiation factor 5-like protein whose sequence is provided in Table 59B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown  
 10 in Table 59b while still encoding a protein that maintains its translation initiation factor 5-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 12% of the bases may be so changed.

These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic  
 15 methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

### NOV60

NOV60 includes two Lynx1-like proteins, designated herein as NOV60a and NOV60b,  
 20 which differ by three amino acids and the relative length of their untranslated regions (UTR's).

#### NOV60a

The disclosed NOV60a (alternatively referred to herein as CG56894-01) includes the 715 nucleotide sequence (SEQ ID NO:215) shown in Table 60A. A NOV60a ORF begins  
 25 with a Kozak consensus ATG initiation codon at nucleotides 348-350 and ends with a stop codon at nucleotides 696-698.

The NOV60a polypeptide (SEQ ID NO:216) encoded by SEQ ID NO:215 is 116 amino acids in length and is presented using the one-letter amino acid code in Table 60B. The Psort profile for NOV60a predicts that this sequence has a signal peptide and is likely to be exported from the cell with a certainty of 0.8200. In alternative embodiments, a NOV60a polypeptide is located to lysosomes with a certainty of 0.1000, or to the endoplasmic reticulum (membrane) with a certainty of 0.1000. The Signal P predicts a likely cleavage site for a NOV60a peptide is between positions 34 and 35, *i.e.*, at the dash in the sequence AQA-SD.

#### NOV60b

The disclosed NOV60b (alternatively referred to herein as CG56894-02) includes the 876 nucleotide sequence (SEQ ID NO: ) shown in Table 60C. A SEC2 ORF begins with a Kozak consensus ATG initiation codon at nucleotides 348-350 and ends with a stop codon at nucleotides 696-698.

The NOV60b polypeptide (SEQ ID NO:218) encoded by SEQ ID NO:217 is 116 amino acids in length and is presented using the one-letter amino acid code in Table 60D. The Psort profile for NOV60b predicts that this sequence is a Type Ia membrane protein, has a signal peptide, and is likely to be localized at the plasma membrane with a certainty of 0.9190. In alternative embodiments, a NOV60b polypeptide is located to lysosomes with a certainty of 0.2000, or to the endoplasmic reticulum (membrane) with a certainty of 0.1000. The Signal P

predicts a likely cleavage site for a NOV60b peptide is between positions 20 and 21, *i.e.*, at the dash in the sequence AQA-SD.

In a search of sequence databases, it was found, for example, that the nucleic acid sequence of this invention has 338 of 424 bases (79%) identical to a gb:GENBANK-ID:AF141377|acc:AF141377.1 mRNA from *Mus musculus* (Ly-6/neurotoxin homolog (Lynx1) mRNA). The full amino acid sequence of the protein of the invention was found to have 92 of 116 amino acid residues (79%) identical to, and 96 of 116 amino acid residues (82%) similar to, the 116 amino acid residue ptmr:SPTREMBL-ACC:Q9WVC2 protein from *Mus musculus* (Mouse) (LY-6/NEUROTOXIN HOMOLOG). NOV60 also has homology to the other proteins shown in the BLASTP data in Table 60F.

15

Elapid snake venom neurotoxins exert their effects through high-affinity interactions with specific neurotransmitter receptors. The lynx1-like gene disclosed herein as NOV60, is highly expressed in the brain and contains the cysteine-rich motif characteristic of this class of neurotoxins. Primary sequence and gene structure analyses reveal an evolutionary relationship between lynx1 and the Ly-6/neurotoxin gene family. Lynx1 is expressed in large projection neurons in the hippocampus, cortex, and cerebellum. In cerebellar neurons, lynx1 protein is localized to a specific subdomain including the soma and proximal dendrites. Lynx1 binding to brain sections correlates with the distribution of nAChRs, and application of lynx1 to *Xenopus* oocytes expressing nAChRs results in an increase in acetylcholine-evoked macroscopic currents. These results identify NOV60 as a protein modulator for nAChRs in vitro, with important implications in the regulation of cholinergic function in vivo.

The NOV60 disclosed in this invention is predicted to be expressed in at least the following tissues: brain. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV60 is provided in Example 2.

The nucleic acids and proteins of NOV60 are useful in potential therapeutic applications implicated in various pathological disorders described further herein, for example, the compositions of the present invention will have efficacy for the treatment of patients suffering from: Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, stroke, tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral disorders, addiction, anxiety, pain, and neurodegeneration, as well as other diseases, disorders and conditions. The NOV60 nucleic acid encoding the lynx1-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. The nucleic acid of the invention encoding a lynx1-like protein includes the nucleic acid whose sequence is provided in Table 60A or 60C, or a fragment thereof.

The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 60A or 60C while still encoding a protein that maintains its Lynx1-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are

5 complementary to the sequence of Table 60A or 60C including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or

10 derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 21% of the bases may be so changed.

The novel protein of the invention includes the lynx1-like protein whose sequence is

15 provided in Table 60B and 60D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 60B and 60D while still encoding a protein that maintains its lynx1-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 21% of the amino acid residues may be so changed.

20 These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

25

#### NOV61

NOV61 is a homolog of the adlcan gene and belongs to the superfamily of cell adhesion molecules. The disclosed NOV61 (alternatively referred to herein as CG56453-01) includes the 5925 nucleotide sequence (SEQ ID NO: ) shown in Table 61A. A NOV61 ORF

30 begins with a Kozak consensus ATG initiation codon at nucleotides 16-18 and ends with a stop codon at nucleotides 5653-5655. The disclosed NOV 70 maps to human chromosome Y.

The NOV61 polypeptide (SEQ ID NO:220) encoded by SEQ ID NO:219 is 1879 amino acids in length and is presented using the one-letter amino acid code in Table 61B. The Psort profile for NOV61 predicts that this sequence has a signal peptide and is likely to be localized outside the cell with a certainty of 0.4371. In alternative embodiments, a NOV61 polypeptide is located to lysosomes with a certainty of 0.1900, to the endoplasmic reticulum (membrane) with a certainty of 0.1000, or to the nucleus with a certainty of 0.1800. The Signal P predicts a likely cleavage site for a NOV61 peptide is between positions 26 and 27, *i.e.*, at the dash in the sequence ALA-CP.

A BLAST analysis of NOV61 was run against the proprietary PatP GENESEQ Protein Patent database. It was found, for example, that the amino acid sequence of NOV61 had high homology to other proteins as shown in Table 61C.

5

| Table 61C. BLASTX results from PatP database for NOV61 |            |                               |
|--------------------------------------------------------|------------|-------------------------------|
| Sequences producing High-scoring Segment Pairs:        | High Score | Smallest Sum Probability P(N) |

In a search of sequence databases, it was found, for example, that the nucleic acid sequence of this invention has 4045 of 4330 bases (93%) identical to a gb:GENBANK-ID:AF245505|acc:AF245505.1 mRNA from *Homo sapiens* (adlican mRNA). The full amino acid sequence of the protein of the invention was found to have 1598 of 1818 amino acid residues (87%) identical to, and 1661 of 1818 amino acid residues (91%) similar to, the 2828 amino acid residue ptnr:SPTREMBL-ACC:Q9NR99 protein from *Homo sapiens* (Human) (ADLICAN). NOV61 also has homology to the other proteins shown in the BLASTP data in Table 61D.

This BLASTP data is displayed graphically in the ClustalW in Table 61E. A multiple sequence alignment is given, with the NOV61 protein being shown on line 1 in a ClustalW analysis comparing the protein of the invention with the related protein sequences shown in Table 61D.

| Table 61E. ClustalW Alignment of NOV61 |                 |                                                              |                                                     |     |     |

The gene of invention is a close homolog of the adican gene and belongs to the superfamily of cell adhesion molecules. Cell adhesion molecules mediate key aspects of development, differentiation, cellular plasticity and physiological function in a variety of tissues. In addition, they are central to a number of disease processes such as cancer. Adican

is a protein that has been described to be elevated in patients with osteoarthritis. Sequence analysis indicates that it is likely to be a secreted protein. A rat gene named mechanical stress-induced protein has been patented and shows significant similarity to adlcan. This protein is elevated in osteoblasts subjected to mechanical stress and has been suggested to be effective in the prognosis, diagnosis or treatment of osteoarthritis. Since this family of proteins seems to have involvement in osteoarthritis, it follows that the protein of invention may share that characteristic.

The disclosed NOV61 of invention has two significant attributes - it is truncated relative to its homolog, adlcan, and secondly, it maps to the Y chromosome. The first attribute is significant in that it is possible that the truncated adlcan-like protein may play a dominant - negative role in the function of adlcan. It is therefore possible that it may constitute an effective treatment for osteoarthritis. The chromosomal localization is relevant because it is known that osteoarthritis has a higher frequency in women. It is possible, therefore, that the truncated protein may be nullifying the effect of adlcan, if any, in males.

The NOV61 disclosed in this invention is predicted to be expressed in at least the following tissues: muscle, lymph. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV61 is provided in Example 2.

The nucleic acids and proteins of NOV61 are useful in potential therapeutic applications implicated in various pathological disorders described further herein, for example, the compositions of the present invention will have efficacy for the treatment of patients suffering from: osteoarthritis, asthma, allergy, muscular dystrophy, Lesch-Nyhan syndrome, myasthenia gravis, hemophilia, hypercoagulation, idiopathic thrombocytopenic purpura, autoimmune disease, allergies, immunodeficiencies, transplantation, graft versus host disease (GVHD), lymphoedema, cancer, tissue degeneration as well as other diseases, disorders and conditions.. The NOV61 nucleic acid encoding the adlcan-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. The novel nucleic acid of the invention encoding a adlcan-like protein includes the nucleic acid whose sequence is provided in Table 61A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 61A while still encoding a protein that maintains its adlcan-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids

whose sequences are complementary to the sequence of Table 61A, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 7% of the bases may be so changed.

The novel protein of the invention includes the adlcan-like protein whose sequence is provided in Table 61B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 61B while still encoding a protein that maintains its adlcan-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 13% of the amino acid residues may be so changed.

These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

## NOV62

NOV62 has homology to neuropsin, an extracellular matrix serine protease. The disclosed NOV62 (alternatively referred to herein as CG56781-01) includes the 834 nucleotide sequence (SEQ ID NO:221) shown in Table 62A. A NOV62 ORF begins with a Kozak consensus ATG initiation codon at nucleotides 31-33 and ends with a TGA codon at nucleotides 808-810. The disclosed NOV62 maps to human chromosome 19.

The NOV62 polypeptide (SEQ ID NO:222) encoded by SEQ ID NO:221 is 259 amino acids in length and is presented using the one-letter amino acid code in Table 62B. The Psort profile for NOV62 predicts that this sequence has a signal peptide and is likely to be localized to the endoplasmic reticulum (membrane) at the plasma membrane with a certainty of 0.5500. In alternative embodiments, a NOV62 polypeptide is located to lysosomes with a certainty of 0.2353, or to the endoplasmic reticulum (lumen) with a certainty of 0.1000. The Signal P predicts a likely cleavage site for a NOV62 peptide is between positions 28 and 29, *i.e.*, at the dash in the sequence TRA-QG.

A BLAST analysis of NOV62 was run against the proprietary PatP GENESEQ Protein Patent database. It was found, for example, that the amino acid sequence of NOV62 had high homology to other proteins as shown in Table 62C.

**Table 62C. BLASTX results from PatP database for NOV62**

| Sequences producing High-scoring Segment Pairs:               | High Score | Smallest Sum     |
|---------------------------------------------------------------|------------|------------------|
|                                                               |            | Probability P(N) |

In a search of sequence databases, it was found, for example, that the nucleic acid sequence of this invention has 747 of 805 bases (92%) identical to a gb:GENBANK-ID:E12348|acc:E12348.1 mRNA from *Mus* sp. The full amino acid sequence of the protein of the invention was found to have 227 of 257 amino acid residues (88%) identical to, and 238 of 257 amino acid residues (92%) similar to, the 260 amino acid residue ptrn:SWISSNEW-

ACC:Q61955 protein from *Mus musculus* (Mouse) (NEUROPSIN PRECURSOR (EC 3.4.21.) (NP)). NOV62 also has homology to the other proteins shown in the BLASTP data in Table 62D.

Table 62F lists the domain description from DOMAIN analysis results against NOV62.

This indicates that the NOV62 sequence has properties similar to those of other proteins known to contain this domain.

5

Neuropsin appears to act as a regulatory molecule in the early phase of LTP via its proteolytic function on extracellular matrix rather than affecting NMDA receptor-mediated calcium increase. The behavioral and electrophysiological abnormalities associated with seizures in epileptic (kindled) mice correspond with those of human epilepsy. In kindled mice, neuropsin was markedly increased in the hippocampus and cerebral cortices. A single intraventricular injection of monoclonal antibodies specific to neuropsin reduced or eliminated the epileptic pattern noted on electroencephalograms and, as a result markedly inhibited the progression of kindling.

Therefore, neuropsin appears to be a key protein controlling pathogenic events in the hippocampus, and thus neuropsin inhibitors might be useful for treatment of epilepsy. Neuropsin has two isoforms, which have been reported to be involved in hippocampal plasticity. The amino acid sequences of the two types of human neuropsin were identical, except that type 2 carried an insert of 45 amino acids at the C-terminus of the leader sequence. The essential three amino acids in the active site triad, His, Asp, and Ser, and the single putative N-glycosylation site were conserved in human and mouse neuropsin. Sequence analysis of the 946 bp genomic DNA spanning the region encoding the insertion sequence revealed that two isoforms were generated in human brain by alternative splicing. However, the mouse genomic sequence did not conserve the 3' acceptor consensus sequence at the corresponding position, suggesting that type 2 neuropsin was a species-specific splice variant. When the open reading frames of human neuropsin were expressed in insect cells, both types of neuropsin were detected in the conditioned media by western blot analysis using anti-human neuropsin serum.

Northern blot hybridization and reverse transcription-polymerase chain reaction showed predominant expression of type 1 neuropsin in pancreas. Type 2 neuropsin was preferentially expressed in human adult brain and hippocampus, although both types were expressed in fetal brain and placenta in comparable amounts. Dot blot hybridization showed that neuropsin was expressed in various regions of adult brain, including the hippocampus and cerebral cortex, and also in various fetal tissues. These results suggest that human type 2 neuropsin may be important to the adult brain plasticity, although both types may be necessary for the development of the nervous system.

The disclosed NOV62 is predicted to be expressed in at least the following tissues: brain. This information was derived by determining the tissue sources of the sequences that

were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV62 is provided in Example 2.

5       The nucleic acids and proteins of NOV62 are useful in potential therapeutic applications implicated in various pathological disorders described further herein, for example, the compositions of the present invention will have efficacy for treatment of patients suffering from: Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, stroke, tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral  
10 disorders, addiction, anxiety, pain, neuroprotection, osteoarthritis, and other diseases, disorders and conditions of the like. The NOV62 nucleic acid encoding the neuropsin-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. The novel nucleic acid of the invention encoding a neuropsin precursor-like protein includes the  
15 nucleic acid whose sequence is provided in Table 62A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 62A while still encoding a protein that maintains its neuropsin precursor-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to  
20 those just described, including nucleic acid fragments that are complementary to any of the nucleic acids just described.

      The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar  
25 phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 8% of the residues may be so changed.

30       The novel protein of the invention includes the neuropsin precursor-like protein whose sequence is provided in Table 62B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 62B while still encoding a protein that maintains its neuropsin precursor-like activities and physiological

functions, or a functional fragment thereof. In the mutant or variant protein, up to about 12% of the bases may be so changed.

These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

### NOV63

NOV63 has homology to the WNT family of proteins. The Wnt gene family consists of at least 15 structurally related genes that encode secreted extracellular signaling factors. WNT proteins function in a range of critical developmental processes in both vertebrates and invertebrates and are implicated in regulation of cell growth and differentiation in certain adult mammalian tissues, including the mammary gland. The disclosed NOV63 (alternatively referred to herein as CG56054-02) includes the 1128 nucleotide sequence (SEQ ID NO: ) shown in Table 63A. A NOV63 ORF begins with a Kozak consensus ATG initiation codon at nucleotides 31-33 and ends with a stop codon at nucleotides 1102-1104. The disclosed NOV63 maps to human chromosome 1.

**Table 63A. NOV63 Nucleotide Sequence (SEQ ID NO:223)**

The NOV63 polypeptide (SEQ ID NO:224) encoded by SEQ ID NO:223 is 357 amino acids in length and is presented using the one-letter amino acid code in Table 63B. The Psort profile for NOV63 predicts that this sequence has a signal peptide and is likely to be exported from the cell with a certainty of 0.3700. In alternative embodiments, a NOV63 polypeptide is located to lysosomes with a certainty of 0.1000, or to the endoplasmic reticulum (membrane) with a certainty of 0.1000. The Signal P predicts a likely cleavage site for a NOV63 peptide is between positions 18 and 19, *i.e.*, at the dash in the sequence ALG-SY.

10

A BLAST analysis of NOV63 was run against the proprietary PatP GENESEQ Protein Patent database. It was found, for example, that the amino acid sequence of NOV63 had high homology to other proteins as shown in Table 63C.

15

**Table 63C. BLASTX results from PatP database for NOV63**

In a search of sequence databases, it was found, for example, that the nucleic acid sequence of this invention has 633 of 795 bases (79%) identical to a gb:GENBANK-ID:AF031168|acc:AF031168.1 mRNA from *Gallus gallus* (*Gallus gallus* Wnt-14 protein (Wnt-14) mRNA). The full amino acid sequence of the protein of the invention was found to have 287 of 349 amino acid residues (82%) identical to, and 319 of 349 amino acid residues (91%) similar to, the 354 amino acid residue ptnr:SWISSPROT-ACC:O42280 protein from *Gallus gallus* (Chicken) (WNT-14 PROTEIN PRECURSOR). NOV63 also has homology to the other proteins shown in the BLASTP data in Table 63D.

5

Wnt-1 (previously known as int-1) is a proto-oncogene induced by the integration of the mouse mammary tumor virus. It is thought to play a role in intercellular communication and seems to be a signalling molecule important in the development of the central nervous system (CNS). The sequence of wnt-1 is highly conserved in mammals, fish, and amphibians.

10 Wnt-1 is a member of a large family of related proteins that are all thought to be developmental regulators. These proteins are known as wnt-2 (also known as irp), wnt-3, up to wnt-15. At least four members of this family are present in *Drosophila*. One of them, wingless (wg), is implicated in segmentation polarity. All these proteins share the following features

15 characteristics of secretory proteins, a signal peptide, several potential N-glycosylation sites and 22 conserved cysteines that are probably involved in disulfide bonds. The Wnt proteins seem to adhere to the plasma membrane of the secreting cells and are therefore likely to signal over only few cell diameters.

The NOV63 disclosed in this invention is predicted to be expressed in at least the following tissues: brain This information was derived by determining the tissue sources of the

sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV63 is provided in Example 2.

5 The nucleic acids and proteins of NOV63 are useful in potential therapeutic applications implicated in various pathological disorders described further herein, for example, the compositions of the present invention will have efficacy for treatment of patients suffering from: Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, stroke, tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral  
10 disorders, addiction, anxiety, pain, neuroprotection, osteoarthritis, and other diseases, disorders and conditions of the like. The NOV63 nucleic acid encoding the WNT-14 precursor-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. The novel nucleic acid of the invention encoding a WNT-14 precursor-like  
15 protein includes the nucleic acid whose sequence is provided in Table 63A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 63A while still encoding a protein that maintains its WNT-14 precursor-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are  
20 complementary to the sequence indicated in Table 63A, including nucleic acid fragments that are complementary to any of the nucleic acids just described.

The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar  
25 phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 21% of the bases may be so changed.

30 The novel protein of the invention includes the WNT-14 precursor-like protein whose sequence is provided in Table 63B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 63B while still encoding a protein that maintains its WNT-14 precursor-like activities and physiological

functions, or a functional fragment thereof. In the mutant or variant protein, up to about 18% of the amino acid residues may be so changed.

These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

### NOV64

NOV64 has homology to dipeptidyl peptidase. The disclosed NOV64 (alternatively referred to herein as CG56884-01) includes the 2660 nucleotide sequence (SEQ ID NO:225) shown in Table 64A. A NOV64 ORF begins with a Kozak consensus ATG initiation codon at nucleotides 44-46 and ends with a stop codon at nucleotides 2633-2635. The disclosed NOV64 maps to human chromosome 17.

**Table 64A. NOV64 Nucleotide Sequence (SEQ ID NO:225)**

A NOV64 polypeptide (SEQ ID NO:226) encoded by SEQ ID NO:225 is 863 amino acids in length and is presented using the one-letter amino acid code in Table 64B. The Psort profile for NOV64 predicts that this sequence has no signal peptide and is likely to be localized at peroxisomal microbodies with a certainty of 0.6400. In alternative embodiments, a NOV64 polypeptide is located to lysosomes with a certainty of 0.1000, or to the cytoplasm with a certainty of 0.4500.

Table 64F lists the domain description from DOMAIN analysis results against NOV64. This indicates that the NOV64 sequence has properties similar to those of other proteins known to contain this domain.

Table 64F. Domain Analysis of NOV64

| gnl Pfam pfam00930, DPPIV_N_term, Dipeptidyl peptidase IV (DPP IV) N-terminal region. This family is an alignment of the region to the N-terminal side of the active site. The Prosite motif does not correspond to this Pfam entry.<br>SEQ ID NO:863 |     |                                                               |                                    |     |  |

NOV64 is a member of the family of dipeptidyl peptidases (DPPs). This group of enzymes catalyzes the removal of dipeptides from the N termini of polypeptides. This novel gene has greatest homology to a recently discovered protein, DPP8 (Abbott et al., Eur J Biochem 2000 Oct;267(20):6140-50). DPP8 in turn is related to DPP4, which is a cell surface peptidase involved in T-cell activation (Kahne et al., Int J Mol Med 1999 Jul;4(1):3-15). Other members of the peptidase family have been targeted as putative drug targets, for instance, in situations where they might cleave polypeptides beneficial in the prevention or reduction of a disease condition.

The NOV64 disclosed in this invention is predicted to be expressed in at least the following tissues: bone, bone marrow, brain (cerebellum, substantia nigra, thalamus), bronchus, cartilage, cervix, chorionic villus, coronary artery, colon, breast, heart, kidney, liver,

lung, lymph node, lymphoid tissue, ovary, placenta, pituitary gland, respiratory bronchiole, retina, skeletal muscle, skin, small intestine, spinal cord, spleen, testis, thymus, thyroid, umbilical vein, urinary bladder, vulva, adrenal gland/suprarenal gland, synovium/synovial membrane, and uterus. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV64 is provided in Example 2.

The nucleic acids and proteins of NOV64 are useful in potential therapeutic applications implicated in various pathological disorders described further herein, for example, the compositions of the present invention will have efficacy for treatment of patients suffering from: Von Hippel-Lindau (VHL) syndrome, Alzheimer's disease, stroke, tuberous sclerosis, hypercalcaemia, Parkinson's disease, Huntington's disease, cerebral palsy, epilepsy, Lesch-Nyhan syndrome, multiple sclerosis, ataxia-telangiectasia, leukodystrophies, behavioral disorders, addiction, anxiety, pain, neuroprotection, osteoarthritis, and other diseases, disorders and conditions of the like. A NOV64 nucleic acid encoding the dipeptidyl peptidase-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed.

The novel nucleic acid of the invention encoding a dipeptidyl peptidase-like protein includes the nucleic acid whose sequence is provided in Table 64A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 64A while still encoding a protein that maintains its dipeptidyl peptidase-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to the sequence of Table 64A, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 37% of the bases may be so changed.

The novel protein of the invention includes the dipeptidyl peptidase-like protein whose sequence is provided in Table 64B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 64B while still encoding a protein that maintains its dipeptidyl peptidase-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 40% of the amino acid residues may be so changed.

These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

#### NOV65

NOV65 includes two dual specificity phosphatase-like proteins, designated herein as NOV65a and NOV65b.

#### NOV65a

A disclosed NOV65a (alternatively referred to herein as CG56651-01) includes the 711 nucleotide sequence (SEQ ID NO: ) shown in Table 65A. A NOV65a ORF begins with a Kozak consensus ATG initiation codon at nucleotides 1-3 and ends with a stop codon at nucleotides 652-654. The disclosed NOV65a maps to human chromosome 1.

The NOV65a polypeptide (SEQ ID NO:228) encoded by SEQ ID NO:227 is 217 amino acids in length and is presented using the one-letter amino acid code in Table 65B. The Psort profile for NOV65a predicts that this sequence is likely to be a Type II membrane protein, and is likely to be localized at the plasma membrane with a certainty of 0.4400. In

alternative embodiments, a NOV65a polypeptide is located to the endoplasmic reticulum (membrane) with a certainty of 0.8500, or to the nucleus with a certainty of 0.7400.

5 *NOV65b*

The disclosed NOV65b (alternatively referred to herein as CG56652-02) includes the 3212 nucleotide sequence (SEQ ID NO: ) shown in Table 65C. A SEC2 ORF begins with a Kozak consensus ATG initiation codon at nucleotides 1-3 and ends with a stop codon at nucleotides 3193-3195. The disclosed NOV65b maps to human chromosome 1.

In a search of sequence databases, it was found, for example, that the nucleic acid sequence of this invention has 328 of 531 bases (61%) identical to a gb:GENBANK-ID:AB027004|acc:AB027004.1 mRNA from *Homo sapiens* (mRNA for protein phosphatase).

- 5 The full amino acid sequence of the protein of the invention was found to have 80 of 174 amino acid residues (45%) identical to, and 115 of 174 amino acid residues (66%) similar to, the 198 amino acid residue ptnr:SPTREMBL-ACC:Q9UII6 protein from *Homo sapiens* (Human) (PROTEIN PHOSPHATASE). NOV65 also has homology to the other proteins shown in the BLASTP data in Table 65F.

Table 65H lists the domain description from DOMAIN analysis results against NOV65. This indicates that the NOV65 sequence has properties similar to those of other proteins known to contain this domain.

5

The NOV65 gene of invention is a member of the family of dual specificity protein phosphatases (DSPs; Martell et al., Mol Cells 1998 Feb 28;8(1):2-11). DSPs recognize either serine/threonine (Ser/Thr) or tyrosine (Tyr) moieties as targets for dephosphorylation. These enzymes regulate mitogenic signal transduction and can thereby regulate the cell cycle. Some members of this family are effective tumor suppressors, for example, PTEN. PTEN is required during embryonic development and later in life, and mutations in this gene give rise to different kinds of inherited and sporadic cancers (Eng, Recent Prog Horm Res 1999;54:441-52; discussion 453). In Drosophila, members of the DSP family, such as puckered, have important roles in development (Martin-Blanco et al., Genes Dev 1998 Feb 15;12(4):557-70). The crystal structure of one member of the DSP family has been elucidated (Yuvaniyama et al., Science 1996 May 31;272(5266):1328-31) and this family has been successfully targeted for small molecule drug development (Ducruet et al., Bioorg Med Chem 2000 Jun;8(6):1451-66). In addition, overexpression of a DSP has been demonstrated to be a potential therapy for cardiac hypertrophy (Bueno et al., Circ Res 2001 Jan 19;88(1):88-96). NOV65 has closest homology to a phosphatase that is differentially regulated in the testis during spermatogenesis

and is therefore thought to be involved in sperm development and maturation (Nakamura et al., Biochem. J. 344 Pt 3, 819-825 (1999)).

The disclosed NOV65 is predicted to be expressed in at least the following tissues: heart, skeletal muscle, colon, fetal lung, head, and ovary. This information was derived by  
5 determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV65 is provided in Example 2.

The NOV65 nucleic acids and proteins of are useful in potential therapeutic applications implicated in various pathological disorders described further herein, for example,  
10 cardiomyopathy, atherosclerosis, hypertension, congenital heart defects, aortic stenosis, atrial septal defect (ASD), atrioventricular (A-V) canal defect, ductus arteriosus, pulmonary stenosis, subaortic stenosis, ventricular septal defect (VSD), valve diseases, tuberous sclerosis, scleroderma, obesity, transplantation, fertility, polycystic ovarian syndrome, cancer, tissue degeneration, bacterial/viral/parasitic infection, systemic lupus erythematosus, autoimmune  
15 disease, asthma, emphysema, scleroderma, allergy, ARDS, muscular dystrophy, Lesch-Nyhan syndrome, myasthenia gravis, Hirschsprung's disease, Crohn's Disease, appendicitis as well as other diseases, disorders and conditions. The NOV65 nucleic acid encoding the phosphatase-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be  
20 assessed. The novel nucleic acid of the invention encoding a protein phosphatase-like protein includes the nucleic acid whose sequence is provided in Table 65A or 65C, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 65A or 65C while still encoding a protein that maintains its protein phosphatase-like activities and physiological functions, or a  
25 fragment of such a nucleic acid.

The invention further includes nucleic acids whose sequences are complementary to the sequence indicated in Table 65A or 65C, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include  
30 chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense

binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 39% of the bases may be so changed.

The novel protein of the invention includes the protein phosphatase-like protein whose sequence is provided in Table 65B or 65D. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 65B or 65D while still encoding a protein that maintains its protein phosphatase-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 54% of the amino acid residues may be so changed.

These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

## NOV66

The disclosed NOV66 (alternatively referred to herein as CG56633-01) includes the 1036 nucleotide sequence (SEQ ID NO:231) shown in Table 66A. A NOV66 ORF begins with a Kozak consensus ATG initiation codon at nucleotides 28-30 and ends with a stop codon at nucleotides 913-915. The disclosed NOV66 maps to human chromosome 3.

A NOV66 polypeptide (SEQ ID NO:232) encoded by SEQ ID NO:231 is 295 amino acids in length and is presented using the one-letter amino acid code in Table 66B. The Psort profile for NOV66 predicts that this sequence is a Type IIIa membrane protein, has a signal

peptide and is likely to be localized at the plasma membrane with a certainty of 0.6400. In alternative embodiments, a NOV66 polypeptide is located to Golgi bodies with a certainty of 0.4600, or to the endoplasmic reticulum (membrane) with a certainty of 0.3700. The Signal P predicts a likely cleavage site for a NOV66 peptide is between positions 17 and 18, *i.e.*, at the dash in the sequence AVS-SD.

In a search of sequence databases, it was found, for example, that the nucleic acid sequence of this invention has 973 of 1036 bases (93%) identical to a gb:GENBANK-ID:AF042089|acc:AF042089.1 mRNA from *Homo sapiens* (chromosome 3, olfactory receptor pseudogene cluster 1, complete sequence, and myosin light chain kinase (MLCK) pseudogene, partial sequence). The full amino acid sequence of the protein of the invention was found to have 192 of 265 amino acid residues (72%) identical to, and 221 of 265 amino acid residues (83%) similar to, the 264 amino acid residue ptnr:SPTREMBL-ACC:O43789 protein from *Homo sapiens* (Human) (OLFACTORY RECEPTOR). NOV66 also has homology to the other proteins shown in the BLASTP data in Table 66D.

Table 66D. NOV66 BLASTP results

Table 66F lists the domain description from DOMAIN analysis results against NOV66. This indicates that the NOV66 sequence has properties similar to those of other proteins known to contain this domain.

5

The olfactory system is able to distinguish several thousand odorant molecules. Olfactory receptors are believed to be encoded by an extremely large subfamily of G protein-coupled receptors. These receptors share a 7-transmembrane domain structure with many neurotransmitter and hormone receptors. They are responsible for the recognition and G protein-mediated transduction of odorant signals. The genes encoding these receptors are devoid of introns within their coding regions. Schurmans et al. (1993) cloned a member of this family of genes, OLFR1, from a genomic library by cross-hybridization with a gene fragment obtained by PCR. By isotopic in situ hybridization, they mapped the gene to 17p13-p12 with a peak at band 17p13. A minor peak was detected on chromosome 3, with a maximum in the region 3q13-q21. After MspI digestion, a RFLP was demonstrated. Using this in a study of 3 CEPH pedigrees, they demonstrated linkage with D17S126 at 17pter-p12; maximum lod = 3.6 at theta = 0.0. Used as a probe on Southern blots under moderately stringent conditions, the cDNA hybridized to at least 3 closely related genes. Ben-Arie et al. (1994) cloned 16 human

OLFR genes, all from 17p13.3. The intronless coding regions are mapped to a 350-kb contiguous cluster, with an average intergenic separation of 15 kb. The OLFR genes in the cluster belong to 4 different gene subfamilies, displaying as much sequence variability as any randomly selected group of OLFRs. This suggested that the cluster may be one of several  
5 copies of an ancestral OLFR gene repertoire whose existence may have predated the divergence of mammals. Localization to 17p13.3 was performed by fluorescence in situ hybridization as well as by somatic cell hybrid mapping.

The ability to distinguish different odors depends on a large number of different odorant receptors (ORs). Sullivan et al. (1996) noted that ORs are expressed by nasal olfactory  
10 sensory neurons; each neuron expresses only 1 allele of a single OR gene. In the nose, different sets of ORs are expressed in distinct spatial zones. Neurons that express the same OR gene are located in the same zone; however, in that zone they are randomly interspersed with neurons expressing other ORs. This distribution suggested to the authors that, when the cell chooses an OR gene for expression, it may be restricted to a specific zonal gene set, but it may  
15 select from that set by a stochastic mechanism. Proposed models of OR gene choice fall into 2 classes: locus-dependent and locus-independent. Locus-dependent models posit that OR genes are clustered in the genome, perhaps with members of different zonal gene sets clustered at distinct loci. In contrast, locus-independent models do not require that OR genes be clustered. To assess the feasibility of these models, Sullivan et al. (1996) determined the expression  
20 zones, sequences, and chromosomal locations of a number of mouse OR genes. They mapped OR genes to 11 different regions on 7 chromosomes. These loci lie within paralogous chromosomal regions that appear to have arisen by duplications of large chromosomal domains followed by extensive gene duplication and divergence. These studies showed that OR genes expressed in the same zone map to numerous loci. Moreover, a single locus can  
25 contain genes expressed in different zones. These findings raised the possibility that OR gene choice is locus-independent or involved consecutive stochastic choices.

Nekrasova et al. (1996) overexpressed human (OR17-4) and rat (olp4) olfactory receptor genes in insect cells, purified them, and characterized them biochemically. They identified monomeric, dimeric, and trimeric forms of the proteins corresponding to molecular  
30 weights of 32, 69, and 94 kD by electrophoresis. The oligomers were resistant to reduction and alkylation and were therefore thought to be held together by SDS-resistant hydrophobic interactions, consistent with observations of other G protein-coupled receptors.

Glusman et al. (1996) described the results of complete sequencing of an OR-rich cosmid spanning the center of the OR gene cluster on 17p13.3. The resulting 40-kb sequence

revealed 3 known OR coding regions, 2 OR genes which may have originated from a tandem duplication event, and a new OR pseudogene fused to another OR gene.

Issel-Tarver and Rine (1996) characterized 4 members of the canine olfactory receptor gene family. The 4 subfamilies comprised genes expressed exclusively in olfactory epithelium.

5 Analysis of large DNA fragments using Southern blots of pulsed field gels indicated that subfamily members were clustered together, and that 2 of the subfamilies were closely linked in the dog genome. Analysis of the 4 olfactory receptor gene subfamilies in 26 breeds of dog provided evidence that the number of genes per subfamily was stable in spite of differential selection on the basis of olfactory acuity in scent hounds, sight hounds, and toy breeds.

10 Issel-Tarver and Rine (1997) performed a comparative study of 4 subfamilies of olfactory receptor genes first identified in the dog to assess changes in the gene family during mammalian evolution, and to begin linking the dog genetic map to that of humans. These 4 families were designated by them OLF1, OLF2, OLF3, and OLF4 in the canine genome. The subfamilies represented by these 4 genes range in size from 2 to 20 genes. They are all  
15 expressed in canine olfactory epithelium but were not detectably expressed in canine lung, liver, ovary, spleen, testis, or tongue. The OLF1 and OLF2 subfamilies are tightly linked in the dog genome and also in the human genome. The smallest family is represented by the canine OLF1 gene. Using dog gene probes individually to hybridize to Southern blots of genomic DNA from 24 somatic cell hybrid lines. They showed that the human homologous OLF1  
20 subfamily maps to human chromosome 11. The human gene with the strongest similarity to the canine OLF2 gene also mapped to chromosome 11. Both members of the human subfamily that hybridized to canine OLF3 were located on chromosome 7. It was difficult to determine to which chromosome or chromosomes the human genes that hybridized to the canine OLF4 probe mapped. This subfamily is large in mouse and hamster as well as human, so the rodent  
25 background largely obscured the human cross-hybridizing bands. It was possible, however, to discern some human-specific bands in blots corresponding to human chromosome 19. They refined the mapping of the human OLF1 homolog by hybridization to YACs that map to 11q11. In dogs, the OLF1 and OLF2 subfamilies are within 45 kb of one another (Issel-Tarver and Rine (1996)). Issel-Tarver and Rine (1997) demonstrated that in the human OLF1 and  
30 OLF2 homologs are likewise closely linked. By studying YACs, Issel-Tarver and Rine (1997) found that the human OLF3 homolog maps to 7q35. A chromosome 19-specific cosmid library was screened by hybridization with the canine OLF4 gene probe, and clones that hybridized strongly to the probe even at high stringency were localized to 19p13.1 and 19p13.2. These clones accounted, however, for a small fraction of the homologous human bands.

Rouquier et al. (1998) demonstrated that members of the olfactory receptor gene family are distributed on all but a few human chromosomes. Through fluorescence in situ hybridization analysis, they showed that OR sequences reside at more than 25 locations in the human genome. Their distribution was biased for terminal bands of chromosome arms. Flow-sorted chromosomes were used to isolate 87 OR sequences derived from 16 chromosomes. Their sequence relationships indicated the inter- and intrachromosomal duplications responsible for OR family expansion. Rouquier et al. (1998) determined that the human genome has accumulated a striking number of dysfunctional copies: 72% of these sequences were found to be pseudogenes. ORF-containing sequences predominate on chromosomes 7, 16, and 17.

Trask et al. (1998) characterized a subtelomeric DNA duplication that provided insight into the variability, complexity, and evolutionary history of that unusual region of the human genome, the telomere. Using a DNA segment cloned from chromosome 19, they demonstrated that the blocks of DNA sequence shared by different chromosomes can be very large and highly similar. Three chromosomes appeared to have contained the sequence before humans migrated around the world. In contrast to its multicopy distribution in humans, this subtelomeric block maps predominantly to a single locus in chimpanzee and gorilla, that site being nonorthologous to any of the locations in the human genome. Three new members of the olfactory receptor (OR) gene family were found to be duplicated within this large segment of DNA, which was found to be present at 3q, 15q, and 19p in each of 45 unrelated humans sampled from various populations. From its sequence, one of the OR genes in this duplicated block appeared to be potentially functional. The findings raised the possibility that functional diversity in the OR family is generated in part through duplications and interchromosomal rearrangements of the DNA near human telomeres.

Mombaerts (1999) reviewed the molecular biology of the odorant receptor (OR) genes in vertebrates. Buck and Axel (1991) discovered this large family of genes encoding putative odorant receptor genes. Zhao et al. (1998) provided functional proof that one OR gene encodes a receptor for odorants. The isolation of OR genes from the rat by Buck and Axel (1991) was based on 3 assumptions. First, ORs are likely G protein-coupled receptors, which characteristically are 7-transmembrane proteins. Second, ORs are likely members of a multigene family of considerable size, because an immense number of chemicals with vastly different structures can be detected and discriminated by the vertebrate olfactory system. Third, ORs are likely expressed selectively in olfactory sensory neurons. Ben-Arie et al. (1994) focused attention on a cluster of human OR genes on 17p, to which the first human OR

gene, OR1D2, had been mapped by Schurmans et al. (1993). According to Mombaerts (1999), the sequences of more than 150 human OR clones had been reported. The human OR genes differ markedly from their counterparts in other species by their high frequency of pseudogenes, except the testicular OR genes. Research showed that individual olfactory sensory neurons express a small subset of the OR repertoire. In rat and mouse, axons of neurons expressing the same OR converge onto defined glomeruli in the olfactory bulb.

Gilad et al. (2000) reported the population sequence diversity of genomic segments within a 450-kb cluster of olfactory receptor (OR) genes on chromosome 17. They found a dichotomy in the pattern of nucleotide diversity between OR pseudogenes and introns on the one hand and the closely interspersed intact genes on the other. They suggested that weak positive selection is responsible for the observed patterns of genetic variation. This was inferred from a lower ratio of polymorphism to divergence in genes compared with pseudogenes or introns, high nonsynonymous substitution rates in OR genes, and a small but significant overall reduction in variability in the entire OR gene cluster compared with other genomic regions. The dichotomy among functionally distinct segments within a short genomic distance requires high recombination rates within this OR cluster.

NOV66 is predicted to be expressed in at least the following tissues: lung, liver, ovary, spleen, testis. This information was derived by determining the tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV66 is provided in Example 2.

The nucleic acids and proteins of NOV66 are useful in potential therapeutic applications implicated in various pathological disorders described further herein, for example, cardiomyopathy, atherosclerosis, hypertension, congenital heart defects, aortic stenosis, atrial septal defect (ASD), atrioventricular (A-V) canal defect, ductus arteriosus, pulmonary stenosis, subaortic stenosis, ventricular septal defect (VSD), valve diseases, tuberous sclerosis, scleroderma, obesity, transplantation, fertility, polycystic ovarian syndrome, cancer, tissue degeneration, bacterial/viral/parasitic infection, systemic lupus erythematosus, autoimmune disease, asthma, emphysema, scleroderma, allergy, ARDS, muscular dystrophy, Lesch-Nyhan syndrome, myasthenia gravis, Hirschsprung's disease, Crohn's Disease, appendicitis as well as other diseases, disorders and conditions. The NOV66 nucleic acid encoding the GPCR-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. A NOV66 nucleic acid of the invention encoding a Olfactory receptor-like protein includes the

nucleic acid whose sequence is provided in Table 66A, or a fragment thereof. The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 66A while still encoding a protein that maintains its Olfactory receptor -like activities and physiological functions, or a fragment of such a nucleic acid.

The invention further includes nucleic acids whose sequences are complementary to the sequence disclosed in Table 66A, including nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 7% of the bases may be so changed.

The novel protein of the invention includes the olfactory receptor-like protein whose sequence is provided in Table 66B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 66B while still encoding a protein that maintains its Olfactory receptor -like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 28% of the amino acid residues may be so changed.

These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

### NOV67

The disclosed NOV67 (alternatively referred to herein as CG56571-01) includes the 1072 nucleotide sequence (SEQ ID NO:233) shown in Table 67A. A NOV67 ORF begins with a Kozak consensus ATG initiation codon at nucleotides 41-43 and ends with a stop codon at nucleotides 989-991. The disclosed NOV67 maps to human chromosome 7.

A NOV67 polypeptide (SEQ ID NO:234) encoded by SEQ ID NO:233 is 312 amino acids in length and is presented using the one-letter amino acid code in Table 67B. The Psort profile for NOV67 predicts that this sequence is a Type IIIb membrane protein, has a signal peptide, and is likely to be localized at the plasma membrane with a certainty of 0.6000. In alternative embodiments, a NOV67 polypeptide is located to Golgi bodies with a certainty of 0.4000, to the endoplasmic reticulum (membrane) with a certainty of 0.3000, or to the mitochondrial membrane with a certainty of 0.3522. The Signal P predicts a likely cleavage site for a NOV67 peptide is between positions 58 and 59, *i.e.*, at the dash in the sequence VRL-HL.

In a search of sequence databases, it was found, for example, that the nucleic acid sequence of this invention has 536 of 649 bases (82%) identical to a gb:GENBANK-ID:AF073974|acc:AF073974.1 mRNA from *Mus musculus* domesticus (*Mus musculus* domesticus clone OR28M olfactory receptor gene). The full amino acid sequence of the protein of the invention was found to have 179 of 311 amino acid residues (57%) identical to, and 228 of 311 amino acid residues (73%) similar to, the 317 amino acid residue ptnr:SWISSNEW-ACC:Q13607 protein from *Homo sapiens* (Human) (OLFACTORY RECEPTOR 2F1 (OLFACTORY RECEPTOR-LIKE PROTEIN OLF3)). NOV67 also has

10 homology to the other proteins shown in the BLASTP data in Table 67D.

5

The olfactory system is able to distinguish several thousand odorant molecules. Olfactory receptors are believed to be encoded by an extremely large subfamily of G protein-coupled receptors. These receptors share a 7-transmembrane domain structure with many neurotransmitter and hormone receptors. They are responsible for the recognition and G protein-mediated transduction of odorant signals. The genes encoding these receptors are devoid of introns within their coding regions. Schurmans et al. (1993) cloned a member of this family of genes, OLFR1, from a genomic library by cross-hybridization with a gene fragment obtained by PCR. By isotopic in situ hybridization, they mapped the gene to 17p13-p12 with a peak at band 17p13. A minor peak was detected on chromosome 3, with a maximum in the region 3q13-q21. After MspI digestion, a RFLP was demonstrated. Using this in a study of 3 CEPH pedigrees, they demonstrated linkage with D17S126 at 17pter-p12; maximum lod = 3.6 at theta = 0.0. Used as a probe on Southern blots under moderately stringent conditions, the cDNA hybridized to at least 3 closely related genes. Ben-Arie et al. (1994) cloned 16 human OLFR genes, all from 17p13.3. The intronless coding regions are mapped to a 350-kb contiguous cluster, with an average intergenic separation of 15 kb. The OLFR genes in the cluster belong to 4 different gene subfamilies, displaying as much sequence variability as any randomly selected group of OLFRs. This suggested that the cluster may be one of several

15

20

copies of an ancestral OLFR gene repertoire whose existence may have predated the divergence of mammals. Localization to 17p13.3 was performed by fluorescence in situ hybridization as well as by somatic cell hybrid mapping.

The ability to distinguish different odors depends on a large number of different odorant receptors (ORs). Sullivan et al. (1996) noted that ORs are expressed by nasal olfactory sensory neurons; each neuron expresses only 1 allele of a single OR gene. In the nose, different sets of ORs are expressed in distinct spatial zones. Neurons that express the same OR gene are located in the same zone; however, in that zone they are randomly interspersed with neurons expressing other ORs. This distribution suggested to the authors that, when the cell chooses an OR gene for expression, it may be restricted to a specific zonal gene set, but it may select from that set by a stochastic mechanism. Proposed models of OR gene choice fall into 2 classes: locus-dependent and locus-independent. Locus-dependent models posit that OR genes are clustered in the genome, perhaps with members of different zonal gene sets clustered at distinct loci. In contrast, locus-independent models do not require that OR genes be clustered. To assess the feasibility of these models, Sullivan et al. (1996) determined the expression zones, sequences, and chromosomal locations of a number of mouse OR genes. They mapped OR genes to 11 different regions on 7 chromosomes. These loci lie within paralogous chromosomal regions that appear to have arisen by duplications of large chromosomal domains followed by extensive gene duplication and divergence. These studies showed that OR genes expressed in the same zone map to numerous loci. Moreover, a single locus can contain genes expressed in different zones. These findings raised the possibility that OR gene choice is locus-independent or involved consecutive stochastic choices.

Nekrasova et al. (1996) overexpressed human (OR17-4) and rat (olp4) olfactory receptor genes in insect cells, purified them, and characterized them biochemically. They identified monomeric, dimeric, and trimeric forms of the proteins corresponding to molecular weights of 32, 69, and 94 kD by electrophoresis. The oligomers were resistant to reduction and alkylation and were therefore thought to be held together by SDS-resistant hydrophobic interactions, consistent with observations of other G protein-coupled receptors.

Glusman et al. (1996) described the results of complete sequencing of an OR-rich cosmid spanning the center of the OR gene cluster on 17p13.3. The resulting 40-kb sequence revealed 3 known OR coding regions, 2 OR genes which may have originated from a tandem duplication event, and a new OR pseudogene fused to another OR gene.

Issel-Tarver and Rine (1996) characterized 4 members of the canine olfactory receptor gene family. The 4 subfamilies comprised genes expressed exclusively in olfactory epithelium.

Analysis of large DNA fragments using Southern blots of pulsed field gels indicated that subfamily members were clustered together, and that 2 of the subfamilies were closely linked in the dog genome. Analysis of the 4 olfactory receptor gene subfamilies in 26 breeds of dog provided evidence that the number of genes per subfamily was stable in spite of differential  
5 selection on the basis of olfactory acuity in scent hounds, sight hounds, and toy breeds.

Issel-Tarver and Rine (1997) performed a comparative study of 4 subfamilies of olfactory receptor genes first identified in the dog to assess changes in the gene family during mammalian evolution, and to begin linking the dog genetic map to that of humans. These 4 families were designated by them OLF1, OLF2, OLF3, and OLF4 in the canine genome. The  
10 subfamilies represented by these 4 genes range in size from 2 to 20 genes. They are all expressed in canine olfactory epithelium but were not detectably expressed in canine lung, liver, ovary, spleen, testis, or tongue. The OLF1 and OLF2 subfamilies are tightly linked in the dog genome and also in the human genome. The smallest family is represented by the canine OLF1 gene. Using dog gene probes individually to hybridize to Southern blots of genomic  
15 DNA from 24 somatic cell hybrid lines. They showed that the human homologous OLF1 subfamily maps to human chromosome 11. The human gene with the strongest similarity to the canine OLF2 gene also mapped to chromosome 11. Both members of the human subfamily that hybridized to canine OLF3 were located on chromosome 7. It was difficult to determine to which chromosome or chromosomes the human genes that hybridized to the canine OLF4  
20 probe mapped. This subfamily is large in mouse and hamster as well as human, so the rodent background largely obscured the human cross-hybridizing bands. It was possible, however, to discern some human-specific bands in blots corresponding to human chromosome 19. They refined the mapping of the human OLF1 homolog by hybridization to YACs that map to 11q11. In dogs, the OLF1 and OLF2 subfamilies are within 45 kb of one another (Issel-Tarver and Rine (1996)). Issel-Tarver and Rine (1997) demonstrated that in the human OLF1 and  
25 OLF2 homologs are likewise closely linked. By studying YACs, Issel-Tarver and Rine (1997) found that the human OLF3 homolog maps to 7q35. A chromosome 19-specific cosmid library was screened by hybridization with the canine OLF4 gene probe, and clones that hybridized strongly to the probe even at high stringency were localized to 19p13.1 and 19p13.2. These  
30 clones accounted, however, for a small fraction of the homologous human bands.

Rouquier et al. (1998) demonstrated that members of the olfactory receptor gene family are distributed on all but a few human chromosomes. Through fluorescence in situ hybridization analysis, they showed that OR sequences reside at more than 25 locations in the human genome. Their distribution was biased for terminal bands of chromosome arms. Flow-

sorted chromosomes were used to isolate 87 OR sequences derived from 16 chromosomes. Their sequence relationships indicated the inter- and intrachromosomal duplications responsible for OR family expansion. Rouquier et al. (1998) determined that the human genome has accumulated a striking number of dysfunctional copies: 72% of these sequences  
5 were found to be pseudogenes. ORF-containing sequences predominate on chromosomes 7, 16, and 17.

Trask et al. (1998) characterized a subtelomeric DNA duplication that provided insight into the variability, complexity, and evolutionary history of that unusual region of the human genome, the telomere. Using a DNA segment cloned from chromosome 19, they demonstrated  
10 that the blocks of DNA sequence shared by different chromosomes can be very large and highly similar. Three chromosomes appeared to have contained the sequence before humans migrated around the world. In contrast to its multicopy distribution in humans, this subtelomeric block maps predominantly to a single locus in chimpanzee and gorilla, that site being nonorthologous to any of the locations in the human genome. Three new members of the  
15 olfactory receptor (OR) gene family were found to be duplicated within this large segment of DNA, which was found to be present at 3q, 15q, and 19p in each of 45 unrelated humans sampled from various populations. From its sequence, one of the OR genes in this duplicated block appeared to be potentially functional. The findings raised the possibility that functional diversity in the OR family is generated in part through duplications and interchromosomal  
20 rearrangements of the DNA near human telomeres.

Mombaerts (1999) reviewed the molecular biology of the odorant receptor (OR) genes in vertebrates. Buck and Axel (1991) discovered this large family of genes encoding putative odorant receptor genes. Zhao et al. (1998) provided functional proof that one OR gene encodes a receptor for odorants. The isolation of OR genes from the rat by Buck and Axel (1991) was  
25 based on 3 assumptions. First, ORs are likely G protein-coupled receptors, which characteristically are 7-transmembrane proteins. Second, ORs are likely members of a multigene family of considerable size, because an immense number of chemicals with vastly different structures can be detected and discriminated by the vertebrate olfactory system. Third, ORs are likely expressed selectively in olfactory sensory neurons. Ben-Arie et al.  
30 (1994) focused attention on a cluster of human OR genes on 17p, to which the first human OR gene, OR1D2, had been mapped by Schurmans et al. (1993). According to Mombaerts (1999), the sequences of more than 150 human OR clones had been reported. The human OR genes differ markedly from their counterparts in other species by their high frequency of pseudogenes, except the testicular OR genes. Research showed that individual olfactory

sensory neurons express a small subset of the OR repertoire. In rat and mouse, axons of neurons expressing the same OR converge onto defined glomeruli in the olfactory bulb.

5 Gilad et al. (2000) reported the population sequence diversity of genomic segments within a 450-kb cluster of olfactory receptor (OR) genes on chromosome 17. They found a dichotomy in the pattern of nucleotide diversity between OR pseudogenes and introns on the one hand and the closely interspersed intact genes on the other. They suggested that weak positive selection is responsible for the observed patterns of genetic variation. This was inferred from a lower ratio of polymorphism to divergence in genes compared with pseudogenes or introns, high nonsynonymous substitution rates in OR genes, and a small but  
10 significant overall reduction in variability in the entire OR gene cluster compared with other genomic regions. The dichotomy among functionally distinct segments within a short genomic distance requires high recombination rates within this OR cluster.

NOV67 is predicted to be expressed in at least the following tissues: brain, testis, ovary, skeletal muscle, neuronal tissue. This information was derived by determining the  
15 tissue sources of the sequences that were included in the invention including but not limited to SeqCalling sources, public EST sources, literature sources, and/or RACE sources. Further expression data for NOV67 is provided in Example 2.

The NOV67 nucleic acids and proteins of are useful in potential therapeutic applications implicated in various pathological disorders described further herein. The  
20 NOV67 nucleic acid encoding the GPCR-like protein of the invention, or fragments thereof, may further be useful in diagnostic applications, wherein the presence or amount of the nucleic acid or the protein are to be assessed. The novel nucleic acid of the invention encoding an olfactory receptor-like protein OLF3-like protein includes the nucleic acid whose sequence is provided in Table 67A, or a fragment thereof.

25 The invention also includes a mutant or variant nucleic acid any of whose bases may be changed from the corresponding base shown in Table 67A while still encoding a protein that maintains its olfactory receptor-like protein OLF3-like activities and physiological functions, or a fragment of such a nucleic acid. The invention further includes nucleic acids whose sequences are complementary to the sequence disclosed in Table 67A, including  
30 nucleic acid fragments that are complementary to any of the nucleic acids just described. The invention additionally includes nucleic acids or nucleic acid fragments, or complements thereto, whose structures include chemical modifications. Such modifications include, by way of non-limiting example, modified bases, and nucleic acids whose sugar phosphate backbones are modified or derivatized. These modifications are carried out at least in part to enhance the

chemical stability of the modified nucleic acid, such that they may be used, for example, as antisense binding nucleic acids in therapeutic applications in a subject. In the mutant or variant nucleic acids, and their complements, up to about 18% of the bases may be so changed.

The novel protein of the invention includes the olfactory receptor-like protein OLF3-like protein whose sequence is provided in Table 67B. The invention also includes a mutant or variant protein any of whose residues may be changed from the corresponding residue shown in Table 67B while still encoding a protein that maintains its olfactory receptor-like protein OLF3-like activities and physiological functions, or a functional fragment thereof. In the mutant or variant protein, up to about 43% of the amino acid residues may be so changed.

These materials are further useful in the generation of antibodies that bind immunospecifically to the substances of the invention for use in therapeutic or diagnostic methods. These antibodies may be generated according to methods known in the art, using prediction from hydrophobicity charts, as described in the "Anti-NOVX Antibodies" section below.

#### NOV68

The disclosed NOV68 (alternatively referred to herein as CG56844-01) includes the 2580 nucleotide sequence (SEQ ID NO:235) shown in Table 68A. A NOV68 ORF begins with a Kozak consensus ATG initiation codon at nucleotides 21-23 and ends with a TAG codon at nucleotides 1896-1898. The disclosed NOV68 maps to human chromosome 9.

A NOV68 polypeptide (SEQ ID NO:236) encoded by SEQ ID NO:235 is 625 amino acids in length and is presented using the one-letter amino acid code in Table 68B. The Psort profile for NOV68 predicts that this sequence is a Type IIIa membrane protein, has a signal peptide, and is likely to be localized at the plasma membrane with a certainty of 0.6400. In alternative embodiments, a NOV68 polypeptide is located to Golgi bodies with a certainty of 0.4600, or to the endoplasmic reticulum (membrane) with a certainty of 0.3700. The Signal P predicts a likely cleavage site for a NOV68 peptide is between positions 25 and 26, *i.e.*, at the dash in the sequence SLA-ET.

A BLAST analysis of NOV68 was run against the proprietary PatP GENESEQ Protein Patent database. It was found, for example, that the amino acid sequence of NOV68 had high homology to other proteins as shown in Table 68C.

**Table 68C. BLASTX results from PatP database for NOV68**

In a search of sequence databases, it was found, for example, that the nucleic acid sequence of this invention has 2128 of 2128 bases (100%) identical to a gb:GENBANK-ID:HUMENDO|acc:J05481.1 mRNA from *Homo sapiens* (Human endoglin mRNA, 3' end).

- 5 The full amino acid sequence of the protein of the invention was found to have 509 of 624 amino acid residues (81%) identical to, and 531 of 624 amino acid residues (85%) similar to, the 658 amino acid residue ptnr:SWISSNEW-ACC:P17813 protein from *Homo sapiens* (Human) (ENDOGLIN PRECURSOR (CD105 ANTIGEN)). NOV68 also has homology to the other proteins shown in the BLASTP data in Table 68D.

Table 68F lists the domain description from DOMAIN analysis results against NOV68.

This indicates that the NOV68 sequence has properties similar to those of other proteins known to contain this domain.

| <u>gnl Smart smart00241</u> , ZP, Zona pellucida (ZP) domain; ZP proteins are responsible for sperm-adhesion to the zona pellucida. ZP domains are also present in multidomain transmembrane proteins such as glycoprotein GP2, uromodulin and TGF-beta receptor type III (betaglycan).
